# *If it's speed you need—*

One trial will prove the advantage of Pratt & Whitney Milling Cutters. No matter what the nature of the work they will give you the highest production the machine is capable of.

They're designed for free, fast cutting. And tempered and seasoned to last longer.

## PRATT & WHITNEY MILLING CUTTERS

Ask us for prices and details on Plain Milling Cutters, Side Milling Cutters, Inserted Blade End and Side Cutters, Screw Slot Cutters, Coarse Tooth Side or Plain Milling Cutters, Involute Gear Cutters, Concave, Convex and Double Angle Cutters, Cutters for Spiral Mills, Roll Thread Die Hobs, Key-Seating and Slotting Cutters, Straight and Spiral Cut End Mills (B. & S. and M. T. Shank), Spiral and Straight Shell End Mills, etc.

And we make formed cutters for special work also. All are backed by the guarantee for goodness that the P. & W. trademark indicates.

# Only Three Minutes to Lace a Belt with the "Clipper"

THE rapid development of Clipper Belt Lacing to its present efficiency ranks with other far-reaching industrial feats which mark the present great world era. Many plant managers recall the not so far distant days when it took from fifteen minutes to half an hour to make a crude, make-shift joint.

Idle machines, workmen at rest, production curtailed (due to belt repairs), are things unknown where Clipper Belt Lacing is used—and its use is world-wide.

The simplicity of the "Clipper" tool eliminates the need of experts. Any workman can successfully lace a belt with it. It makes a hinge-joint of perfect smoothness on both sides of the belt. The joint hugs the pulley, runs true, and is extremely durable. "Clipper"-laced belts develop maximum power. The larger plants keep "Clipper" tools and hooks handy to every battery of machines. "Clipper" Belt Lacing is real economy, real efficiency — the speediest known to industry.

The "Clipper" is sold under a perpetual guarantee and goes to responsible parties for free trial.

*Most mill supply houses sell the "Clipper." Dealers not stocking it write for particulars*

"Little David" Hoist Serving a Boring Mill.

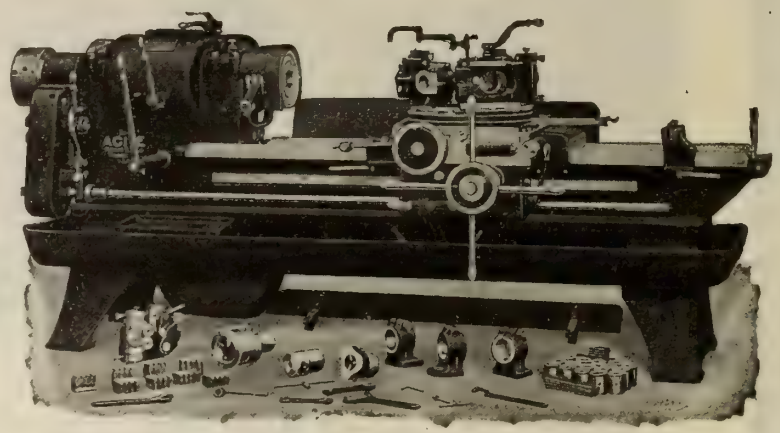
## *"RUNNING MATES"*

## The "Little David" Air Hoist
and
## The Heavy Machine Tool

In heavy machining operations your big expensive lathe, planer, slab miller, or boring mill often stands idle, while the work is being lifted, set-up or moved around.

You can make these machines more efficient by reducing this non-productive time. Use a "Little David" Motor Air Hoist; they are simple, easy to install, and easy to operate, and quickly pay for themselves in productive time saved. Capacities up to 10,000 lbs. and lifts up to 20 feet.

**Bulletin 8106 describes Little David Hoists and bulletin K-602 CIRCO Straight Lift Air Hoists. Send for them both.**

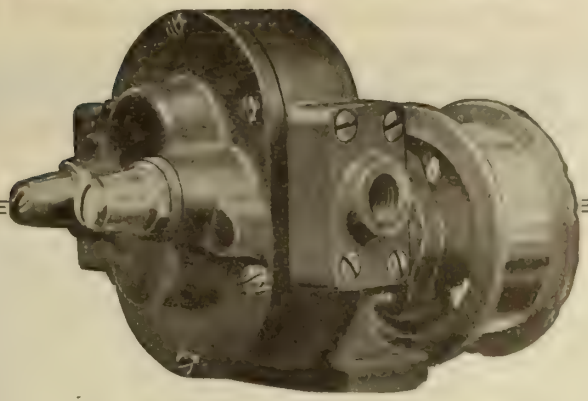


**Canadian Ingersoll-Rand Company, Limited**

**Sydney Sherbrooke Montreal Toronto**
**Cobalt Winnipeg Nelson Vancouver**

## Efficiency Demanded! Not Merely Desired

In those wonderfully organized shops where every machine is made to do its best, where the slightest increase in established production cost is rigidly guarded against, where efficiency in every sense of the word is obtained; it is in these shops you will find Cincinnati Acme Turret Lathes and Screw Machines.



Indifferent machines may serve their purpose in shops of the same type. But—*are they good enough for you?* Send for our catalog and decide with the facts before you.

# THE JOHNSON FRICTION CLUTCH

## Put Johnson Clutches on Your Machines

The tight and loose pulley is passing from favor. With all its disadvantages, it long survived because a reliable friction clutch was not in evidence.

But in the Johnson Clutch, builders of high grade machinery have found a real clutch service. It has been thoroughly tested and adopted on the finest machines made.

Replace your tight and loose pulleys with Johnson Clutches.

*New Truths and Old Fallacies*

# Fusibility of Alloys—*Continued*

## HARDNESS OF ALLOYS

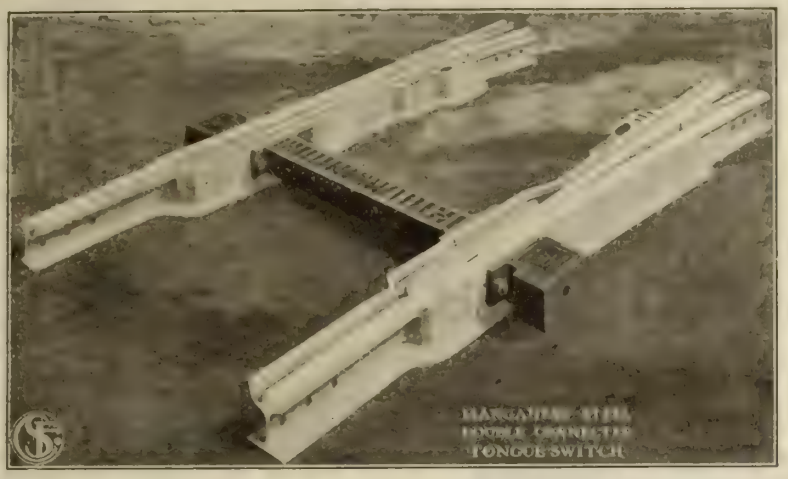
The foregoing brings us to the discussion of the relative hardness of White Metal Alloys.

Many babbitt users lay great stress upon obtaining extra hard metals; usually specifying tin base metals with high copper content. We shall submit, further on, some comparative figures which do not bear out the usually accepted belief in that connection, and are as subversive in their way as are the figures relating to the melting points of metals. These figures do not sustain the reputation of copper as a hardener, nor of the superior hardness of tin base metals.

They also disclose the fact that if a babbitt's value depends upon its hardness, the lowest grades of babbitt would sustain the load put upon a majority of bearings, which rarely exceed 500 pounds per square inch, and often much less.

Extreme hardness can only be obtained at the expense of malleability. The hardest babbitt is a lead base metal containing a high percentage of antimony, which is quite brittle, and, therefore, its use is confined largely to Rolling Mill and other similar bearings where the lining is thick and securely backed to prevent the metal cracking.

Magnolia is often loosely characterized as being a soft metal. This is doubtlessly due to its velvety feeling to the touch, a less metallic ring than Genuine and its being easier to break. Not even the Brinell test is a safe guide in determining the relative resistance of babbitts under a crushing strain. In fact, there is a surprisingly small difference in the sustaining powers throughout the entire list of babbitts in general use.



Continued next month.

# FORD-SMITH

# If it's a Special Machine We Can Make it

## Here's an Example of Our Work!

ONE of our customers, a large motor firm, required a special miller for milling their transmission cover. We designed and built the machine here illustrated. Something new and special; now running every day and getting the required output.

## We Can Make You Any Style of Machine

THIS cut shows but one of many cases where we have rendered real service to prominent manufacturers of Canada in building high-grade machines economically and efficiently. It is not necessary to send across the line for your special machines, no matter how intricate. We can make any style of machine you desire.

Our engineering staff is at your service for all manner of designing, and with our modern machine tool plant we are in a position to build from the smallest to the largest machines required for manufacturing purposes.

**If you have a manufacturing problem we would like to solve it. Write us and we will promptly confer with you.**

More than five million "American" Pulleys now save power in efficient plants here and abroad.

**AMERICAN STEEL SPLIT PULLEYS**

Write for book, "Getting Maximum Pulley Efficiency." It is free.

## TO SERVE is the function of this Engineering Staff—

THE tremendous sale of "American" Pulleys exemplifies the correctness of the principle that he who serves best sells most.

One reason for the unprecedented success of the "American" is that we were never so eager to sell it as we were to make certain that it was right according to every approved principle of power transmission.

The value of the American Pulley Engineering Service to you will be particularly emphasized, if you are confronted with an *unusually* difficult driving problem.

The engineers who comprise this service will welcome an opportunity to frankly discuss your transmission problems with you regardless of whether a sale may or may not result — their interest is solely centered in rendering you efficient service.

**For name and address of nearest Agent, see Donnelley's Red Book, on file at all leading libraries, national banks and hotels.**

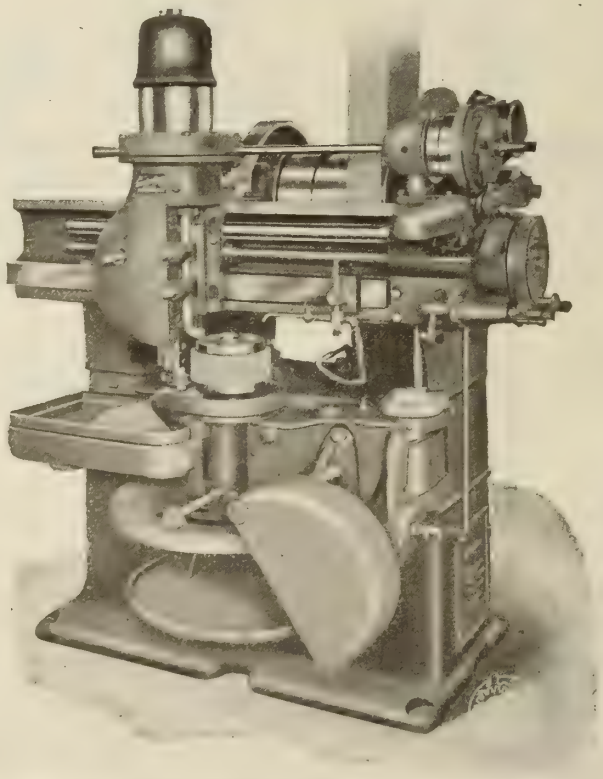
# Gear Cutting With the "IFS" Left Out

## The Gear Shaper Way

A production manufacturer knows that he will secure good gears IF he has an accurate cutter, an accurate machine and a machine working on the correct principle. The whole question of good gears is resolved in this one little word "IF."



When the Gear Shaper was originally designed, the question of "IF" was taken into consideration and every possible means known to mechanical engineering was employed to eliminate the "IFS" from gear cutting.

That we have been successful in solving the problem is evidenced by the fact that each ensuing year sees a larger number of manufacturers adopting the Gear Shaper method.

How the Gear Shaper has accomplished this is clearly explained in our general catalog "Commercial Gear Cutting," which is a treatise on the subject of:—

Gear Cutting with the "IFS" Left Out.

**Send for your copy to-day.**

The Fellows Gear Shaper—the machine which has taken the "IFS" out of gear cutting.

# The Comfortable Way to Protect Eyes

## STOCO SAFETY GOGGLES

(Pat. Dec. 12, 1916)

*with*

## "CELOGLAS" Shatter-Proof Lenses

A safety goggle may be efficient in every other respect, but if it cannot be put on and then forgotten; if it cannot be worn day in and day out for long hours at a stretch without irritating the nose or tiring the eyes; if, in short, it is not thoroughly comfortable, it is not a practical protection glass—neither is it a STOCO Safety Goggle.

The patented one-piece front construction of the STOCO Safety Goggle, in addition to increasing the protection afforded (see illustrations) makes possible a very wide, smooth bridge, which comfortably distributes the weight of the goggle over a wide area instead of uncomfortably concentrating it on the sensitive bridge of the nose. This feature, combined with the light weight of the STOCO Safety Goggle, results in a protection glass that is truly comfortable.

Celoglas Shatter-Proof Lenses—laminated lenses which cannot shatter into the eye—are plane and practically colorless so that they cannot tire or strain the eyes. (Incidentally, STOCO Safety Goggles may be worn over regular glasses if desired.)

If you are responsible for the buying of eye protection for your shop or plant and have not yet found a really comfortable protection glass, we suggest that you try out the STOCO Safety Goggle. A request on your own or your firm's letterhead will bring you a sample by return mail. There will be no charge or obligation.

## THE STANDARD OPTICAL CO.
## GENEVA, N.Y. U.S.A.

# The City of ST. JOHNS QUEBEC

## Locate in this Real Transportation Centre

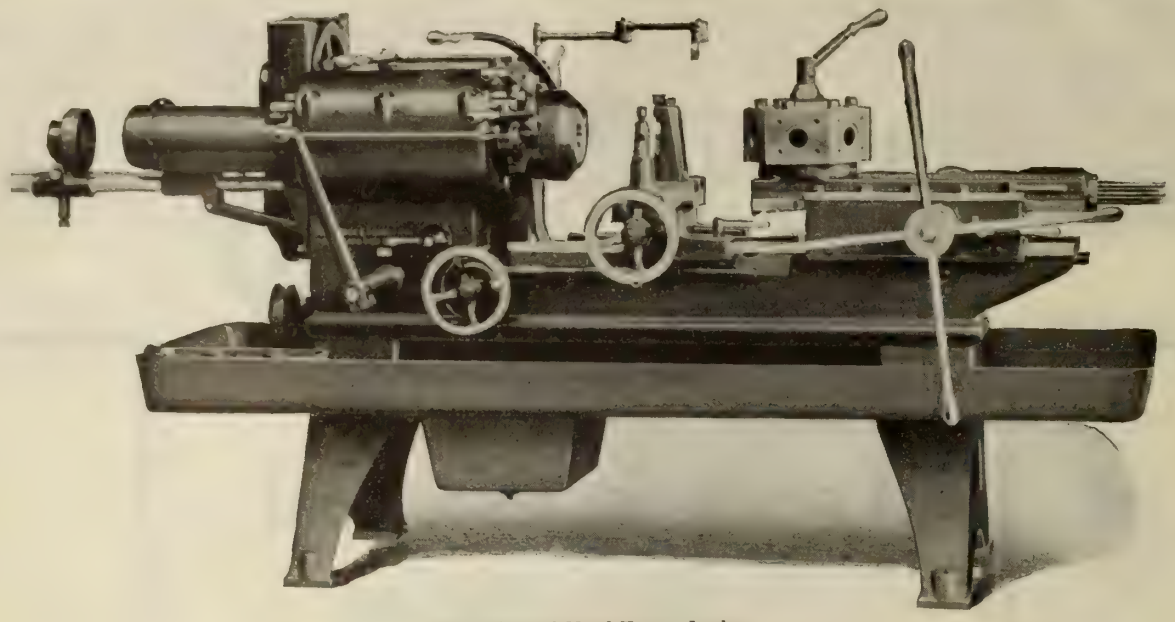
St. Johns is a nerve centre of the network of railways connecting Central and Western Canada with the Maritime Provinces and with the Eastern States. Seven railways, including the C.P.R. and G.T.R., run through the city and are interconnected in the St. Johns yards by a terminal switching company. The manufacturer locating in St. Johns enjoys the advantages of competitive freight rates and dispatch in the assembling of raw materials and distribution of the finished product. The city in fact commands lower freight rates and a cheaper coal supply than any other centrally located manufacturing city on the North American continent.

St. Johns is directly connected by rail with the Montreal docks, 27 miles distant, affording first-class facilities for foreign trade. The city is an ideal location for the American manufacturer opening a branch plant in Canada; having direct connections by water with New York, the St. Lawrence and Great Lakes and the Eastern Seaboard of the United States.

Unlimited electric power is developed at Chambly, eleven miles north-east of the city, and distributed at prices that will compete with any city or town in the Dominion.

Cheap living conditions and low rents and taxes have resulted in cheap labor and an abundant supply of both skilled and unskilled workers is always available. Labor troubles are quite unknown.

In addition to the natural advantages of St. Johns as an industrial site the city also offers extraordinary inducements, such as: Tax exemptions; street extensions; bonus of five per cent. on your payroll for five years, making it an unusual industrial opportunity.



*Without a knowledge of your business or the conditions affecting it, we do not claim that St. Johns is rationally your location; but we know that St. Johns possesses extraordinary advantages, that in all probability it is the best site for your plant from every point of view, that you will be running the risk of serious mistake if you do not include this city in your investigations.*

*Seven railroads, including Canada's great transcontinental lines.*
*Finest ocean shipping facilities.*
*Canal connections with New York, the Eastern States, and the Great Lakes.*
*Cheapest labor market in Canada.*
*Plentiful supply of skilled and unskilled labor.*
*Cheap and abundant electric power.*
*Cheap coal and lower freight rates.*
*Desirable factory sites with all public conveniences immediately available.*
*Extraordinary inducements to new industries.*

No. 6 Geared Head Turret Lathe

# The New Nos. 4 and 6 Geared Head Turret Lathes

## Features:

1—Double the power obtained by cone drive.

2—Double the spindle speeds—twelve through this type head—instead of six using the customary 3 step cone.

3—Motor (constant speed) may be mounted on the head geared direct, or with chain or belt drive to driving shaft.

4—Considerable time saved in changing speeds.

5—All steel gears run in oil bath and lubricate the bearings by splash.

6—With the additions of the heavy duty carriage the No. 6 provides more productive capacity than any similar size machine obtainable to-day.

These turret lathes fill an ever increasing demand for machines to take heavy facing and forming cuts, long drilling operations in the solid—for machining alloy steel gear blanks as well as providing the best solution for direct motor drives.

With their wide diversity of feeds and speeds, these turret lathes are flexible enough to embrace the feeds and speeds ideal for operating on the many different metals in use to-day and for facing, forming and cutting off operations on all diameters within the capacities of the machine.

| Capacities | No. 4 | No. 6 |
|---|---|---|
| Swing over bed | 16″ | 20 3/8″ |
| Swing over carriage slide | 7″ | 9 1/4″ |
| Automatic Chuck Capacity | 1 1/2″ | 2 1/4″ |
| Length that can be turned | 10″ | 12″ |

# BRIGGS MILLERS

## *Production Tools*

Machine tools to-day are judged by their ability to do efficient work, save time, labor and expense. These have ever been the measures by which Briggs Millers have been designed and constructed. That our engineers have succeeded in meeting these requirements is evidenced by the increasing popularity of Briggs Millers.

No matter what the nature of the work or how severe the service the Briggs Miller will stand up to it. Its unusual rigidity, great strength and ability to take wide deep cuts when running at a high rate of speed, has established a wide reputation that is unexcelled. We would like to show how "Briggs" adaptability and convenience can increase output and lower costs for you. A letter will bring full details by return mail.

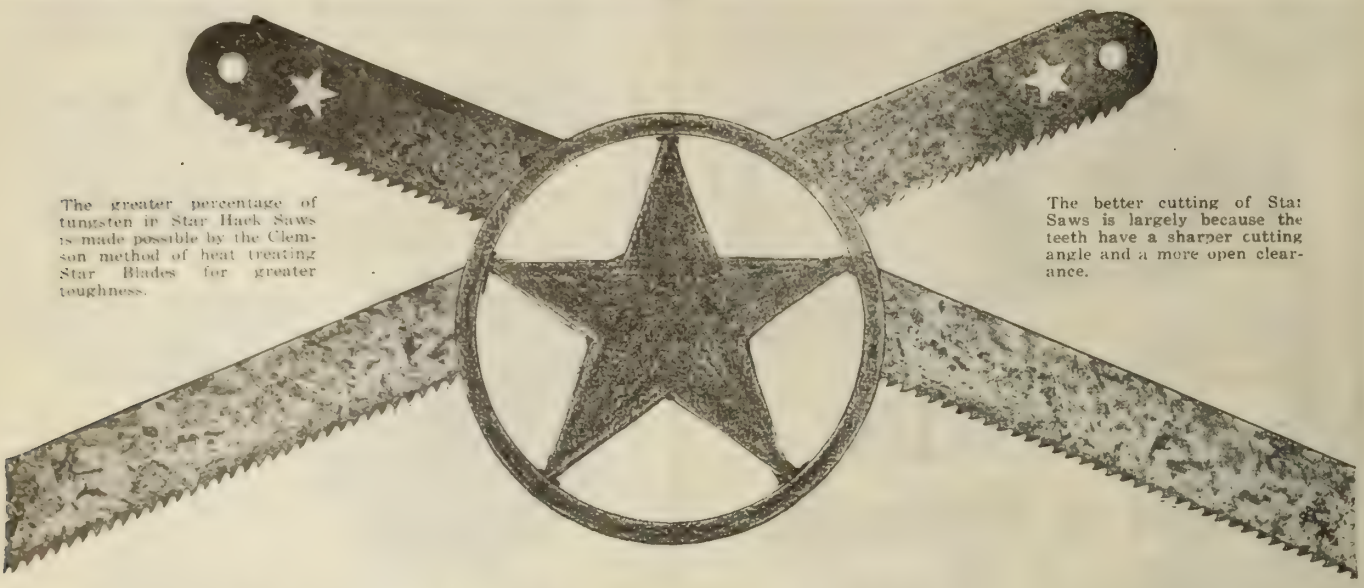
# 100 Per Cent. Production

THE New Landis Piston Grinding Machine meets both essentials 100 per cent. strong.

A brief summary of the principal features and what they accomplish in better pistons and greater production:

Cylinder part and relief, ground complete without removing from the machine, insuring concentricity of all grinding operations. Work practically remains in plane with grinding wheel centre at all times as the work swings directly over the fulcrum point. A number of different sized or shaped cams can be placed in attachment at the same time, thus enabling different shaped pistons to be ground with slight adjustment.



Universal driver furnished with each attachment, facilitating round and accurate work.

**Write to-day for complete description.**

# *Does It Pay to Order Just*
# "HACK SAW BLADES?"

Many hack saw users grow careless. They order just "hack saw blades."

Because it has been the standard blade for 35 years, most dealers will fill this order by sending you Star Saws, but —

It doesn't pay to take the chance. You might get fooled some day by receiving an inferior saw blade. It's much safer to specify "Star," every time.

The poorer blade will mean a loss, both in time and material that will amount to much more than the difference in price between Star and ordinary blades.

Slow cutting blades waste valuable time not only in cutting but in frequent changing. They run up your production costs and cut down your profits more than many manufacturers realize.

Ordinary blades have the old "wood saw" tooth and two-way clearance. Star blades have an undercut tooth and three-way clearance that are made for cutting the hardest metal and do a variety of work that is impossible with ordinary blades.

Star saws prove their better quality very quickly in two ways — they will go through metal that other blades refuse to cut. And one Star blade will cut a far wider variety of sizes, shapes and metals than is possible with ordinary saws.

Make these two tests yourself with Star saws and you will never be satisfied to have other blades used in your shop. Our service men will be glad to help you solve your production problems on Hack Saws if you will write us.

**STAR SAWS NOW SOLD BY THE MAKERS**

We now sell our own product for we believe no other organization is in such a good position to give selling service on Star Saws as our own factory that has made them for 37 years.

We are not satisfied only to sell you Star Blades but stand ready to render you every service in getting the best results in their use.

# Snapped While on the Job

Heald Style No. 60 Cylinder Grinder.

## 600-Pound Cylinder as a Test

Innumerable jobs of all kinds are submitted to our Engineering Service Department. Here is a 600-pound cylinder with a hole 6¾ dia. x 20″ long. Two cylinders are to be ground, two reamed, and the four connected, after running a while, disassembled for examination and comparison.

***If it is too far to send samples, send prints. We can work from them.***

Heald Style No. 65 Cylinder Grinder.

## A Manufacturing Proposition

You cannot afford to take chances in reaming cylinders or using any grinder not built expressly for the purpose. 85% of the automobile manufacturers are grinding their cylinders and using Heald machines.

To increase production, the Heald Company have just designed a new cylinder grinder which is a single purpose machine for manufacturers. This Heald No. 65 shown grinding a Stutz cylinder was built primarily for production of massive and heavy work, but it will handle single and two enbloc cylinders equally as rapidly.

***Eighty-five per cent. of the motor manufacturers grind. Are you one of them?***

Heald Style No. 70 Automatic Internal Grinder.

## Grinding Large Radii on Tubing Dies

Grinding tubing dies called into use the radius truing device which can be furnished on either the style No. 70 or No. 75. The dies were of various sizes requiring special shaped wheels that not only had a radius but part of the face was straight.

**No matter how odd your work is, send in a quantity of samples or blue prints. Our experience is yours for the asking.**

# STEINLE

## Full Swing Side Carriage Turret Lathes

*Standard 24-in. belt driven lathe. Furnished in 4-in. or 6¼-in. spindle bore, with or without oil pans, and with standard or special tooling equipment.*

## TIME—Floor to Floor—4½ Minutes Each

THE MACHINE was a standard 24-in. Steinle Turret Lathe with 4-in. spindle bore arranged for belt drive, and equipped on turret with boring bars and special overhead bar carrying a turning tool and on cross slide carriage with a special three-cutter tool block.

THE WORK was an 18-in. cast iron gas engine flywheel. The surfaces machined included boring hub with bars, rough turning rim with special overhead bar carrying turning tool, and shaving and facing both sides of rim with a three-cutter tool block on cross slide carriage.

Just one more record of rapid production on a machine designed and built for fast severe service in producing accurate work economically.

And this record is maintained not on one or two pieces, but on lots of several hundred—just steady, consistent production under average shop conditions.

***Do your records compare with this?***

***Why not send us your blueprints and let our Engineering Department determine what can be done on your own work, or ask to have a qualified representative call and go thoroughly into the matter?***

# For SPEED use

# LARCUL CUTTING OILS

**Show us a job on which you are using ordinary cutting oils and we will show you how to get MORE speed. Here are three letters from users of Larcul. They speak for themselves:**

"On a Gould & Eberhardt, also B & L Milling Machines. Milling Cutter 6 in. diameter, 28-tooth, 8 in. wide. Stock 60 degrees carbon, 16% tungsten. Cutter speed 157 feet per minute. Milling cut across cutter 8 in. Time—8 minutes. Finish glass smooth and sharp."

"Used Larcul Amber on Acme Automatic. Stock 40-50 degrees carbon, 7% nickel. Long bolt size 4¾ in. Blank cut in 1 minute 9 seconds. Threading 12 seconds. Speed 150 surface. Spindle speed 500 R.P.M. The carbon steel chasers used for threading, averaging 3,000 pieces per day, stand up three and four days."

"We carefully compared the results obtained with the use of Larcul Ebony against a competitive brand on low carbon steel. The job was that of broaching a two-way key-lock. With Larcul Ebony we obtained 10,000 pieces as against 1,000 with the other brand."

Larcul Cutting Oil is made in two grades, AMBER, a transparent oil, for all types of automatics, turret machines, gear cutters, etc., and EBONY, for pipe and bolt threading, nut tapping, turrets, automatic turning and boring, etc.

## *You pay 100% for service*

### *. . . and but 25% for the metal that will measure its life*

YOU get the service paid for . . . uninterruptedly, or in installments—with repeated renewals or repairs as the metals used stand up to the work.

Economically then, metals used in parts manufacture assume greater value than just 25% of apparatus costs.

Monel Metal, used in power plant apparatus as valve trim, turbine blading, pump rods and liners, etc., where resistance to high heats, erosion and corrosion is vital to service delivery, has more than justified its cost both as raw material and finished product. For the manufacturer by employing Monel has purged his apparatus of weaknesses that compel expensive repairs, costly shut-downs, and repetitive purchases of new machines.

The very toughness of Monel that in some cases will slightly raise manufacturing costs is pledge of its ability to deliver service continuously.

Monel Metal is absolutely untouched by rust, is strong as steel, resists the eating action of most alkalies and acids. Monel retains its strength under high heats that break down the very structure of most metals and successfully withstands the eroding action of high pressure and superheated steam.

The name Monel is given to a line of metal products produced by The International Nickel Company from a natural nickel alloy—67% nickel, 28% copper and 5% other metals. These products include Monel blocks, Monel rods, Monel castings, Monel wire, Monel strip stock, Monel sheets, etc. The name Monel identifies the natural nickel alloy as produced by The International Nickel Company.

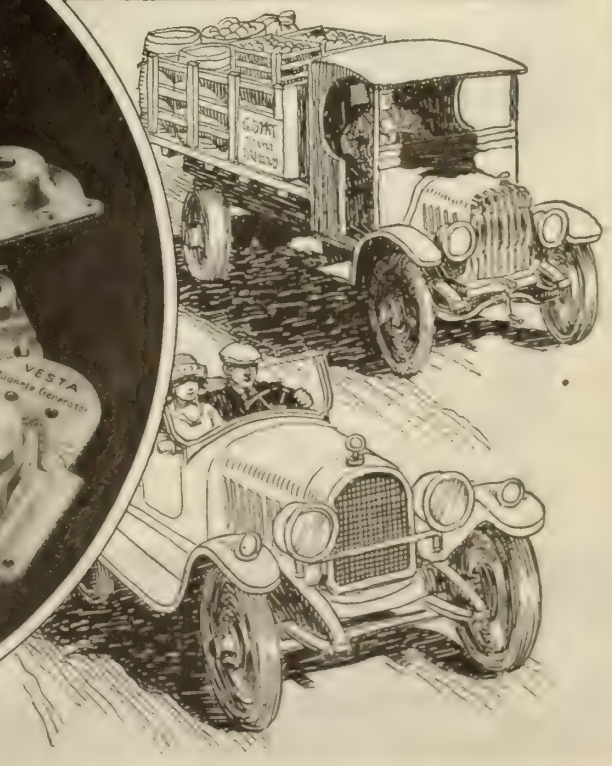
# Progress in Transportation

THE modern automobile, truck, motorcycle and aeroplane would have been impossible had not manufacturing methods kept pace with the demand for progress in transportation.

Franklin Die-Castings have played an essential part in this development, and today they fill an important place in the specifications for automobiles and accessories.

Ever since 1892, when we established the die-casting industry in this country, we have been adapting die-castings to numberless lines of manufacture, and our nearly 30 years' experience is at the disposal of progressive engineers.



We cast in aluminum, tin, lead and zinc base alloys, and quote from samples or blueprints.

# PACKINGS

Take packings—rod and sheet—away from the industries, and even the most inexperienced knows what would happen.

With the operation of practically all kinds of plants, factories, mills, etc., so utterly dependent on rod and sheet packings to allow proper operation, why use any but thoroughly reliable and well-known products?

### DANIEL'S P. P. P. ROD PACKING

Probably the best known rod packing on the market. Unequalled for the packing against steam, water, air, ammonia, and other fluids.

Many practical tests by experienced engineers under various conditions have clearly demonstrated that P.P.P. is the most economical rod packing to use. Its long life is remarkable, its ability to create a saving in the fuel bill is well known.

*"The Story of Some Friction Test"*

is a booklet that should be in the hands of everyone who has anything to do with rod packing, whether buyer or user.

### EBONITE SHEET PACKING

Used exclusively in many of the largest power houses, factories, and machine shops, for high pressures, super-heated steam, hot water, ammonia, oils and acids and all other kinds of joints requiring packing.

EBONITE will hold a vibrating joint absolutely tight, and where there is a varying expansion or contraction of the pipes EBONITE is especially desirable.

# Precision Grinding Principles and Experience

When C. H. Norton dictated the material published in "Principles of Cylindrical Grinding" he said it consisted of "valuable facts and directions suggested by long experience with cylindrical grinding."

Facts suggested by experience constitute an important part of Norton service—to both grinding wheel users and grinding machine users. They are facts which help cut down costs, increase production and get longer and better service out of Norton Wheels and Norton Machines.

If the Norton experience is worth anything to you, you are welcome to it. It covers a broad field. You can obtain only a small portion of it in booklet form, but it is part of a valuable assistance which is being rendered the grinding industry every day — assistance based on long experience.

Some of these booklets may interest you and help you. In case you are in need of the more profitable help of the practical men who have been gathering the experience, this branch of Norton Service is yours upon request.

## A National Institution of Mechanical Service

IN Canada, as in every country in the world, there are names which, through years of service, have warranted national confidence and good-will. In the Canadian world of mechanical and engineering efficiency there is one name which enjoys the distinction of leadership. Its prestige carries through the entire coast-to-coast chain of sales offices and warehouses into every city, town, and hamlet.

Fairbanks-Morse products mark the farmer, the manufacturer, the artisan, and all users as careful and practical buyers of mechanical goods. The Fairbanks-Morse 100% quality seal is the buying guide for the consumer—the guarantee of satisfaction.

The Canadian Fairbanks-Morse general catalogue is a reference of what is standard in design and practice in mechanical goods. This book lists the largest variety of scales, valves, steam goods, oil engines, pumps, electrical machinery, machine tools, woodworking machinery, transmission appliances, railway contractor's and machine shop supplies ever published in Canada in one book: Your copy will be sent on request.

# Designing Fixtures for Holding Pistons

## Preferences of Designer—Thickness of Wall—Accuracy of Finish Desired—Material Used—All These Points Have a Varying Influence on the Design of the Holding Arrangement

By F. SCRIBER

AS a means of propulsion nothing to-day is more common or more fundamental to this end than pistons which are as most everyone knows one of the basic units in automobile engine design and aircraft engine design not to mention innumerable other forms of engines, etc. Therefore, it will no doubt be interesting to study some of the designs of holding-fixtures which are used for machining the same on chucking machines, engine lathes and various other forms of special rigid machines for turning these. Apart from the preferences of the individual designer which of course are more or less of an item in themselves the very nature of the piston such as thicknesses of walls, accuracy of finishes desired and material used have a varying influence on the design on the holding arrangement.

In Fig. 1 we have a piston 2 3-4 inches diameter made entirely of steel with thin walls of .060 inches thick at the open end of the piston. This piston was machined all over both inside and out except for a very small portion in back of the bosses which carry the connecting rod wrist pin. The fixture used for holding this after the piston had been machined inside and while the outside was turned and the piston ring grooves cut and end faced was mounted on a turret lathe, the body of this fixture being indicated at A; this was made of cast iron.

In this body was driven a steel portion B which was keyed in place; the piston was slipped over the diameter C against shoulder D, this bar being flatted off at E to clear the bosses of the piston. The square headed screw E is tightened by the operator and this coming against the beveled pin F forces pin G against a tapered end H, which in turn forces out four pins I, which equalize on the diameter J, thus securely holding the outer end of the piston against the strains of cutting. Three screws K, against which comes spring L, keep the four pins back against the beveled surfaces of the operating pin, while spring M forces the other pins back after the screw has been released, thereby permiting the piston to be removed upon completion of the cutting. At X in this illustration is shown the tool used for turning the outside of the piston, other tools used at this time being cutters held in front and rear cross-slide blocks on the machine for grooving and facing.

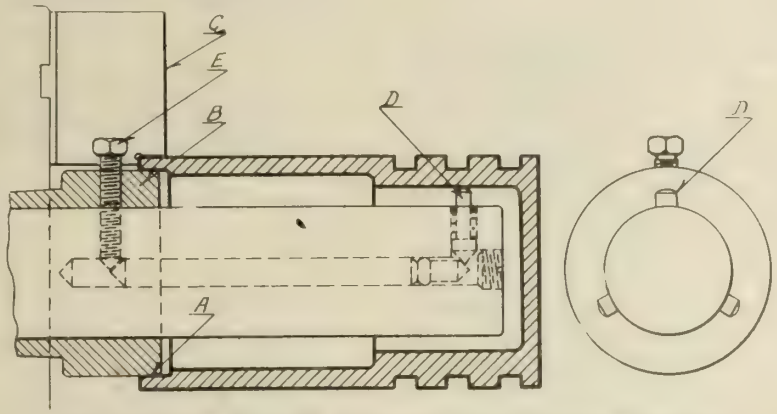

FIG. 2 PISTON HOLDER ARRANGED WITH CHUCK AS DRIVER.

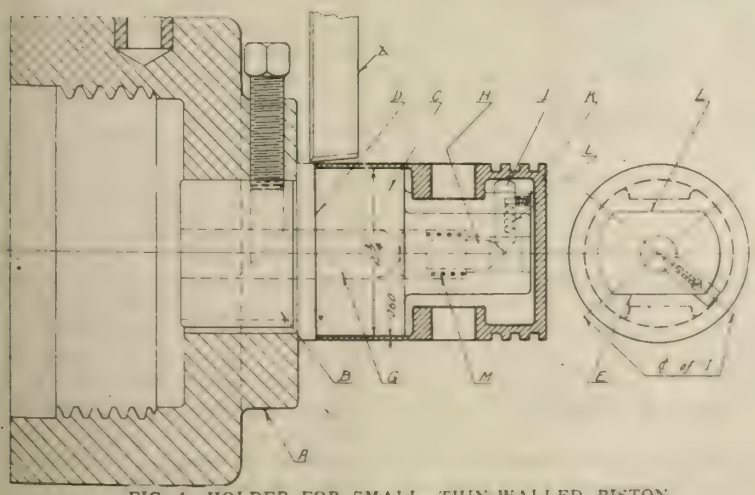

FIG. 1 - HOLDER FOR SMALL, THIN-WALLED PISTON.

In Fig. 2 we have an example of an arrangement, which although somewhat similar to the preceding, was used for machining the outside of a heavy cast iron piston. In this design of piston the diameter at A was first bored, also the chamber, while the outside of the open end was turned to the correct diameter for a length equal to the machined portion of the inside diameter. The piston was next pushed over a suitable holder B in the spindle of the machine and three soft jaws C in a chuck grip the piston at the open end over this holder. To hold the closed end steady and centralize it three pins D, which are expanded

by the screw E in the same manner as in the design previously described, are employed.

A holding device of different design is illustrated in Fig. 3. In this arrangement the piston is machined at X following which it is placed on the fixture shown, which consists of a cast iron body A screwed on the spindle nose of the turret lathe upon which is mounted a steel ring B over which the piston fits. Before this operation the hole for the connecting bar wrist pin has been bored out and through this hole is placed a pin C which also goes through a bar D. In the end of this bar D a draw rod E is threaded which goes through the spindle of the machine and at the outer end is attached a hand wheel F, in the end of the spindle is placed a bushing G and by turning the hand wheel the draw rod is caused to screw into the connection, thereby pulling the piston by means of the pin in the wrist pin holes securely back on the fixture.

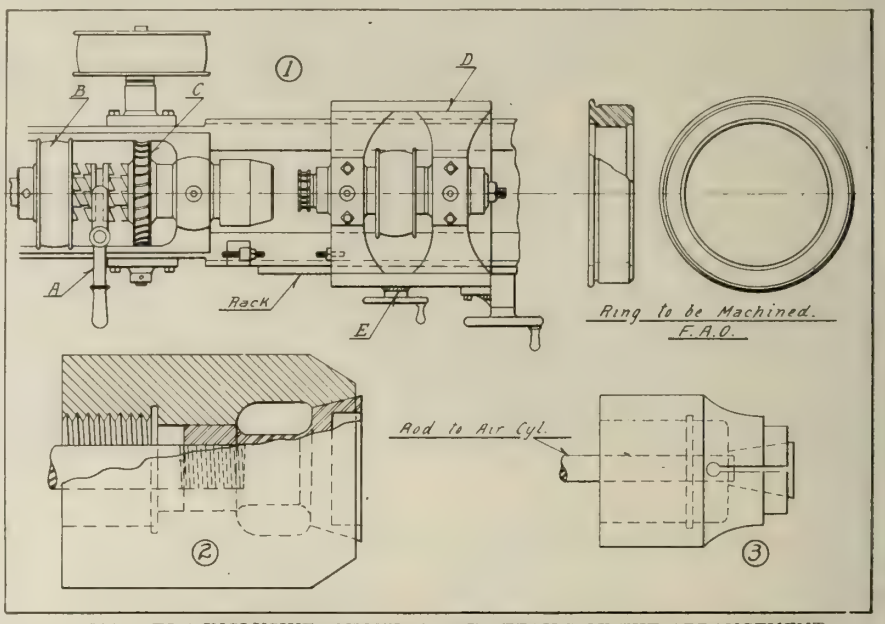

Fig. 5 shows an illustration of an arrangement having the same design except that as the wrist pin hole in the piston is not bored a double hooked bar is made to straddle the wrist pin hole bosses, therefore by tightening the hand wheel A at the end of the spindle through the medium of the drawback rod the hooked bar is caused to draw back into the spindle nose fixture thus pulling the piston securely against the seat C on the body of the fixture D. To compensate for the irregularities in the rough cast bosses of the piston this hooked bar E is made a floating fit in the holder. Small hand knob E is pinned to the end of the drawback rod, the advantage of this being to turn the hooked bar by means of the draw rod half way round so it will clear the bosses while the piston is put in position or removed. These four arrangements shown are all good designs which have proven satisfactory for making the parts shown. These particular holders were used for machining in quantities, they varying in diameter from the 2 3-4 size up to approximately 10 inches.

## MACHINE FOR MILLING SPECIAL WASHERS

By G. Barrett

The accompanying sketch illustrates a special machine designed for milling steel rings for ring spinning frames. The rough rings are made on the Ajax forging machine, from solid round bars, and are afterwards faced to the desired width on a vertical mill. They must have a very smooth finish to prevent the cotton yarn from sticking during the spinning process. The machine here shown accomplished this with very good results and gave quick and accurate production. After facing, the rings are held in the collet chuck shown enlarged in Fig. 2. When trueing up the ring the clutch lever A is thrown over so that the clutch engages with the pulley B, which revolves the work spindle at high speed.

When ready for machining the clutch is engaged with the worm wheel C, this worm wheel being driven by means of a worm underneath on which the driving pulley is secured, the latter being operated by a quarter turn belt. An adjustable stop is provided for locating the carriage in the proper position when milling. The cutter is first fed to the desired depth, using the graduation on the cross feed spindle. The work spindle is allowed to make about three revolutions before the work is completed. Machining the outside is done in the same manner, the periphery being milled while the ring is held from the inside in the chuck shown in Fig. 3. The work produced from this machine was entirely satisfactory.

FIGS. 1 TO 3 INCLUSIVE—SHOWING THE DETAILS OF THE ARRANGEMENT.

## PROTECTING POLISHED METALS

A process has been invented in Germany for protecting polished metals which have to undergo annealing. As a rule, tarnishing results, but in this case the trouble is overcome through the use of a solution of boric oxide.

The solution is only applied as a very thin film over the articles to be annealed, but it is claimed that it completely excludes atmospheric oxygen. The film melts at a temperature varying between 550 and 650 deg. Cen., according to its composition, and acts as a protection so long as it remains solid. Steel, for example, remains bright when heated to the melting point of the composition, and no coloration takes place when the steel is tempered. It is stated to be still more effective in the molten or semi-molten condition, as it then forms a perfectly gas-tight cover round the article, even when heated to the highest temperature used in practice. The coating is perfectly fireproof, does not evaporate, and dissolves any oxidised matter on the surface of the heated metal. The coating can be applied either as a powder, sprinkled or dusted over the surface of the objects to be annealed, or as a liquid. It is soluble in water and methylated spirit, and the work to be annealed is simply dipped in the solution and allowed to dry. The coating peels off on cooling, or it may be dissolved in warm water.

## Making Cold Rolled Strip Steel—Rolling of Tin Plate—How to Obtain Best Results When Rolling Thin Sheet, and What Happens When Unequally-heated Pack is Inserted in the Rolls

By W. S. STANDIFORD

IN our December 26th issue, we told of the English and American methods of rolling, how to obtain large output when rolling their plates, also how to avoid waste. We also described the plain and universal type of mills, and how to obtain the best results from each. In this, the concluding part of the article we will start at the making of cold rolled strip steel.

### Cold-Rolled Strip Steel

Another class of thin sheet steel for which there is a large demand is called "cold-rolled" strip steel and "ribbon-stock." The manufacture of this grade of metals differs radically from that of sheet steel; the red-hot steel billets first being reduced to a sufficiently thin gauge and width in a hoop or band mill, there being no cross rolling of the metal as is the case in sheet steel manufacture. It is made into coils in the hoop mill and goes to the cold-rolling department or is sold in the market in coil form. Hot rolling of steel in the hoop mill leaves the pores of the metal in an open or porous condition, no matter how smooth the bands look on their surfaces. On the other hand cold-rolling closes the pores and makes a denser product. The rolling of strip steel and ribbon stock is mostly done on rolls that generally have a body length of 8 or 12 inches, the roll diameter varying from 6 to 10 inches. Of course there are longer and thicker rolls used for the purpose of obtaining wider strips, but the average sized mill uses the small sizes of rolls listed above.

Strip mill rolls are turned or ground with a curve on their surfaces that is entirely opposite to those used for manufacturing hot rolled thin sheets; rolls for producing the latter require a concave surface, the deepest part being in the middle, while the ribbon stock and strip steel rolls must be slightly convex or crowned, the amount of crowning varying with their length and diameter. For small rolls of from 8 to 12 inches body length, the convexity varies from 0.001 to 0.015 inch high in their centres. This allows for spring or bending of the rolls which is necessarily heavy on cold rolling mills as contrasted with hot ones, the rule being that longer rolls require more crowning than do short body ones.

The degree of finish on hot mill rolls need not be nearly as smooth as that on the cold rolls. The surface on the former is sufficiently smooth as the roll lathe tool leaves it, but cold rolls require a shining body exterior and they also must be as free from surface scratches as possible, otherwise each scratch or mark will show on every strip or ribbon of steel that is run through the mill. The rolls should produce a bright shining finish on the strips and leave a surface that can be directly nickel-plated without the necessity of the metal having to be further buffed or polished.

By finishing the ribbon stock bright much time and expense are saved the consumer who regularly uses quantities of this steel. It is the usual practice of mills manufacturing cold-rolled ribbon or strip stock to anneal this metal between gauge reductions in cold rollings; and, contrary to the general opinion held among those uninitiated in rolling mill procedure, the temper is obtained not by annealing but by cold rolling after annealing, and it is at this stage of manufacture that the skill of the strip maker reaches its pinnacle of perfection.

**PRACTICAL KNOWLEDGE**

*The author, being a practical man himself, can tell his story in everyday rolling mill language. He touches no technicalities, but tells the tale simply, concisely, and briefly. An article of this nature should be filed away for future reference, as we do not know very much, as a general rule, about rolling mill practice.*

Five different degrees of hardness or tempers are produced by cold rolling. They are as follows: dead soft; soft; medium soft; half hard or bright rolled and full-hard. When the strip is thoroughly annealed the metal comes under the dead soft classification, and it is capable of being used for the most difficult of deep stampings or drawings. It is very much superior to the usual grades of sheet steel made for drawing purposes; its better quality being due to the fact that it has not been cross-rolled and also to the numerous cold rollings needed to reduce it to the desired thickness, the many cold rollings received making its texture very fibrous in character and increasing its tensile strength and ductility. The soft grade is for making ordinary kinds of bends and easy drawing operations in which a certain amount of stiffness is desired in the finished article. The medium soft quality is intended for use where a springy metal is desired, one capable of standing bending at right angles across its grain; it should also bend fairly well with the grain without breaking.

The hard, or full hard, as it is usually named, is the strips cold rolled to size and not annealed. This metal is intensely hard and it is only suitable for flat work such as for making washers, discs, and other flat work where no bending is needed. In purchasing strip steel always specify the gauge in thousandths of an inch or by Birmingham or Stubs gauge and not by the U. S. standard gauge. Mills making strip steel can furnish it in either wide sheets, which can be cut into strips of the desired width by the consumer or else it can be obtained in strips of the required width.

When stripper dies are used in certain kinds of stamping work it is best to use the sheared metal, as more accurate straight-edges are procured. The drawback to the strips that are rolled to proper width is that the middle parts of the sides of strips are bulged outward, it not being square and at a right angle to the top and bottom sides, so that for use in stripper die work it is not so good. The edges of the sheared strip will usually contain slight burrs on the edge of one side, which is made by the slitting knives. Strip steel is also used for making brake bands in the automobile trade, proving to give good service in that capacity. Strip steel is always oiled and boxed, or wrapped in burlap so as to prevent scratches and surface rust in shipping.

### Rolling of Tin Plate

In the rolling of tin plate, which is made mostly out of the semi-finished steel bars, there is a loss of metal in the heating and rolling from the semi-finished to the finished form of from 6 to 8 per cent. Rolls for making tin plate are generally shorter in length than those used to roll heavier plates, such as those used for ships and boilers. The curvature of surface in the latter rolls are not as deep as the tin plate rolls. On account of the thinness of the gauge of metal rolled and the fact that no water is used on tin plate rolls, the latter require a deeper concave surface to allow for expansion. When a mill first starts rolling tin plates on a Monday morning it is customary to roll narrow sheets until the roll centres have expanded and are level, when wide sheets can be rolled. The bars from which these plates are rolled are 8 inches wide, and vary in thickness from $\frac{3}{8}$ to $\frac{5}{8}$ of an inch; the length varying according to the widths of the finished plates desired.

### Turning of Tin Plate Rolls

In the turning of tin plate rolls, both rolls could be turned with a concave sur-

face, but it is found advisable in practice to turn one roll with a plane surface and put double the concavity in the other as the roll turning is done quicker by this method. After the plane surfaced roll is turned, the other one intended to have a concave surface is put into the lathe. The roll having a level surface is next put in the carriage on top, and the top roll is crossed so that their centres are out of line. This makes the middle part of each roll approach nearer to one another than their ends, the rolls being placed as close to each other as is practicable without the top roll revolving by friction. Narrow cuts are then taken from the centre of the roll, each cut being about 1½ inches wide. The top roll during the process of turning is let down so as to touch the roll in the lathe, from time to time, until the roll in the lathe has a curved surface and no light can be seen between the two rolls when they are touching.

The amount of crossing varies with the length and thickness of the rolls and also the time cycle of working. Where two 12-hour or three 8-hour shifts are worked, the usual amount of crossing is as follows: Rolls of 24-inches diameter by 32 inches long should be crossed 2¼ inches. Rolls 38 inches long and 24 inches diameter require a 2½ inch crossing; 24 inch diameter rolls having a length of 40 inches need a 2⅝ inch crossing. If rolls have a length of 48 inches it will only be necessary to cross them 2⅝ inches as this amount will be found by experience to be amply sufficient. This length of roll does not require so much crossing as some other sizes on account of the mill crew not being able to work wide sheets as fast as they can handle narrow ones, consequently the rolls do not attain such a high temperature as narrower rolls do. In regard to rolling 34 inch wide sheets on rolls having a body length of 48 inches, the rolls having been crossed in the lathe 2¾ inches, and rolling this width of sheets continuously it has been found that the necks of the rolls will heat too much and more than their centres, the result being that the pack of sheets will not lay flat and open easily.

### Getting the Best Results

To get the very best results in thin sheet rolling the top roll should be two inches smaller in diameter than the bottom one. The top roll, by reason of its having a smaller diameter, bites deeper into the pack of sheets, and as it has a slower rate of rotation its surface speed, differing from that of the bottom roll, produces the result that the pack of sheets lies flat and opens up easier. Sheet rolls should not be worked at too high a temperature as they are liable to crack, in fact, many sheet mill rollers crack such rolls by working them at too high a heat, the management not knowing any better, putting the cracking down to accidental causes instead of its being due to the roller's carelessness, as the former, by heating the rolls too suddenly and by having the ends of the rolls vary too much in temperature from their centres can cause the best rolls made to crack. Rolls once cracked soon break in two. When rolls have a deep blue color in their centres and the ends are purple, the centres being about 600 degs. Fahr., this is the highest temperature that they should be allowed to get, as they are almost certain to break or develop fire cracks and have pieces break out of the surface. They also have a burned or rough surface. Chilled rolls used on finishing sheet mills are made from cast iron and have their chilled surfaces ¾ inch deep, while the rest of the roll is soft cast iron. The combining of soft centre rolls having a chilled outside surface makes considerable trouble in the hot rolling process as the expansion of the chilled structure of cast iron is about double that of the soft gray iron centre. Should the roll be permitted to heat too rapidly the expansion will tear the roll in two, which is due to the different amounts of expansion between the chilled and soft iron.

Cast iron, when heated, has a certain amount of permanent expansion, and it never contracts back to the original size when it is cold, but always remains slightly larger than it was before heating. This causes the grain of the metal to become porous in consequence. The greater the depth of chill on a roll the greater the expansion will be. When a chilled roll has been reduced in diameter by frequent dressing it loses its power of expansion, the result being that the roll turner has to put less concavity in the roll.

### Two Important Points

There are two important points that a sheet steel roller has to contend with in the rolling of the above metal. The first is to make the pack of sheets open easily; the second is to make them lay flat when finished. The second is the more difficult, as to make a heat of sheets lay perfectly flat is not an easy thing to do. The roller may work the screws on housings exactly alike on each pack of sheets, yet each one will have a different shape when finished. You will have one sheet curved or dished like a saucer, another pack of sheets will buckle, and the sheets composing another pack will draw to one side, all of them being made in the same heat. Uneven heating in the furnace will cause the pack of sheets while they are in the rolls to run off to one side. The heater placed the packs in the furnace, and when they were partially heated they were turned up on their edges. The sides of the pack being upward and in the open part of the furnace they were more exposed to the heat and flames than the sides at bottom of furnace. Thus one side or edge of the pack soon acquired a greater temperature than the other, which may vary from 25 to 50 degrees.

### What Happens

When an unequally heated pack is inserted in the rolls, the hot side, or that side in which the temperature has been raised above the other, will pull faster and move ahead of the other sections. This causes the sheets to shift their positions on one another in the pack and to pinch, buckle and show stress marks. By getting the metal too hot in the furnace and the heat evenly distributed over the pack surface, the latter will be

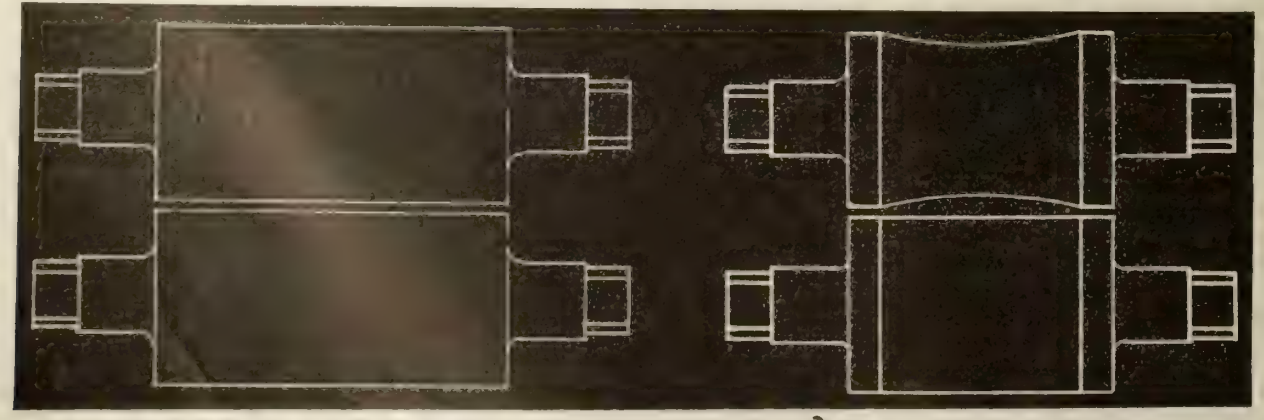

FIG. 3 ROLLS FOR MAKING HEAVY PLATES ON AMERICAN-STYLE MILLS. THE ROLLS ARE TURNED FLAT, AND RUNNING WATER IS USED TO PREVENT THE ROLLS' EXPANSION.

FIG. 4—HEAVY ENGLISH PLATE MILL ROLLS WHICH ARE WORKED DRY. THE ONE ROLL CARRIES ENOUGH CURVATURE TO SAVE TURNING. CONCAVE SURFACE IS EXAGGERATED TO SHOW THE IDEA CLEARLY.

full of scale, and if the rolls are worn slightly hollow in the middle (which is generally the case toward the end of a week's run) the scale will be pushed along towards the centres of the plates and become embedded in the metal, which soon causes trouble in the pickling department, as the pickling fluid will eat into and dissolve the metal on the smooth parts of the plates long before the scale is removed by the acid. This never occurs when the sheets contain very little scale upon their surfaces. From the foregoing it will readily be noted the importance of a correct heating temperature, especially when rolls are worn slightly hollow in their centres.

The turning of chilled iron rolls for manufacturing thin sheets such as are used for making cooking utensils, etc., is in general a very tedious operation, and attempts have been made to do this work by means of specially constructed grinding machines. This is a great success, both from an economical and quality standpoint. The grinding of rolls can be done in about half the time it takes a roll-turner to turn them on the lathe, while the rolls ground on the machine have a smoother finish than any lathe tool will make, they being more accurately level in every respect. Sometimes a jam in the rolls will cause what is technically known as a "burnt spot." Its shape varies, depending on the form of the material rolled. These burnt spots occur on hot mill rolls only. In sheet mill rolls these hard places take the form of a long streak of compressed chilled iron, extending parallel to the axis of the roll, their depths varying from 1-32 to ⅛ of an inch.

### Chilled Cast Iron Rolls

Chilled cast iron is the hardest metal a roll turner has to work. The tool used is very little harder than the chilled iron. In order to cut any metal at all and give the tool a chance to do the cutting, a roll has to revolve at a very slow speed in the lathe, its periphery moving at a rate of one-half a revolution per minute. When a burnt spot is encountered, owing to the metal getting compressed by the sudden stoppage of the rolls, the compressed metal is rendered as hard as the metal in the tool, if not harder, the result being that when the tool strikes the hard spot the edge of tool breaks out, sliding over the top and refusing to cut at all. To get over this trouble he must sharpen his tool, put it in a lathe, take a very light cut until the burnt spot nears, then sudednly take a very heavy cut so as to get under it and lift it out. When it is ⅛ inch deep it has to be broken down little by little, as a roll-turning tool will not take a deep cut in ⅛ inch chilled iron. Doing this work is tedious and dangerous as pieces of the spot and turning tool fly out into the air with very great force. The writer has seen a roll turner have an artery pierced in his arm from this source. It is hardly necessary to say that after pressing the lever down to make the tool take the "lifting-out" cut, that a roll turner doesn't stay in the vicinity of the lathe, but retires about eight feet to one side.

After the work is completed a roll is made 3-16 to ⅜ inch smaller in diameter, it also being out of round shape, and the large amount of metal required in the turning out of the hard spot being wasted. The turning tool is also ruined until it is dressed and put into shape by a blacksmith. There are cases in which the tool is rendered totally unfit by breaking into several pieces, so that it wouldn't pay a blacksmith to spend any time upon it. It will be seen from the above that it is absolutely necessary to cut the burnt spot entirely out of a roll in order to obtain a smooth surface. When an emery wheel roll grinder is used the emery wheel being very much harder than any burnt spot in a chilled iron roll, the compressed metal is very easily and quickly ground with the rest of the roll's surface, only enough metal requiring to be removed to smooth up the roll's periphery. The burnt spot having a smooth surface like the rest of the roll, it does not interfere with manufacturing good plates. Roll-grinding machines are money savers and their use is increasing every year.

The writer knows of mills where the rolls are necked in the usual manner in a lathe, the necks in such cases being left 1-32 inch oversize, then they are ground to their correct diameter in a roll grinder.

### Ground Roll Necks

Ground roll necks, owing to their perfection in finish and roundness, make the rolls operate very much better in the mill housings than when they are turned in a roll lathe, thus a roller is enabled in starting a new order to set his rolls much quicker and maintain the desired gauge thickness easily. The reasons controlling this factor are due to the fact that, no matter how sharp a necking tool is used in a roll lathe, the necks of all rolls are always, to a certain extent, out of true cylindrical shape, as the roll-turning tool in lathes of this character requires to be operated below the roll's centre and thus it exerts an upward thrust against centres and wears them slightly oval in shape. An emery wheel on a roll grinder on the other hand requires only a slight pressure against the work, the grains of emery in the wheel touching the roll's surface at a very narrow angle and being far harder than any tool and travelling at a fast speed, soon reduces the necks to a true cylindrical shape. On this account rolls having perfect journals revolve better in the mill housings, there being no high spots on them to grind the bearings to an uneven shape.

In the handling of rolls for making thin sheets, the roller has to use judgment if one set of rolls are smooth and the other rough. Thus, if the roughing rolls are freshly dressed and smooth, while the surfaces of the finishing ones are rough—by this it is meant that they have been in use for some time—the finished sheets will have a rough and spotty appearance. If the roughing rolls have a rough surface and the finishing rolls are smooth and the reductions of metal on the latter are sufficient to remove the roughing roll surface marks, the finished sheets will be smooth. Of course, in a case of this kind the finishing rolls will not keep smooth for as long a time as when both the roughing and finishing sets are freshly dressed and put into a mill at the same time. The foregoing shows that a roller on a sheet mill has no cinch while making sheet iron, steel, etc., and he has to be continually on his guard and use judgment as each lot of metal rolled behaves in a different manner while being rolled.

### Should Be Perfect As Possible

Where steel or iron sheets are to be coated with tin they require to be as perfect as possible from all buckles and blemishes, as every imperfection will show on the finished product when the tin plate dipper gets through with his work. The dipper also plays an important part in turning out smooth-appearing sheets, it being possible on his part —if the pickling and dipping into the molten tin is not done carefully—to produce a very rough and uneven-looking coating, which may be blamed upon the quality of sheets coming from the mill, when in reality the fault is with the tin dipper. To test whether a sheet of tin plate is evenly coated, lay it on a flat surface and place the eyes at a height of about two inches from its top and look diagonally over it from one corner to another. If it has a good level and even coating of tin, it will be free from waves and spots, if otherwise the defects will be easily seen. Should such a sheet be looked directly down upon from its top, nothing but its largest defects will show as the reflection from the bright surface will interfere with seeing the small waves of unequally deposited tin

### A FEW POINTS TO REMEMBER

*Strip mill rolls are turned, or ground, with a curve on their surfaces that is entirely opposite to those used for manufacturing hot rolled thin sheets.*

*The degree of finish on hot mill rolls need not be as great as that on cold rolls.*

*It is good practice to anneal cold-rolled ribbon stock, or strip stock, between gauge reductions in cold rollings.*

*Five different degrees of hardness are produced by cold rolling, dead soft, soft, medium soft, half hard or bright rolled, and full hard.*

and spots. By glancing over a sheet diagonally with the eyes occupying a low position, shadows will be cast by each ridge of tin, due to uneven flowing.

The part played by the roll designer in these days of efficiency methods is most important, as the rapid progress in mechanical arts is due, to a great extent, to the roll designer, who is often called upon by various inventors and mechanical engineers to design rolls for making difficult sections in iron, steel and also the non-ferrous metals. In those early days when the iron and steel industry was in its infancy there were no roll designers or foremen roll turners; the designing of rolls being usually done by the roller, a draftsman, mill superintendent, or foreman machinist, who generally made a rough sketch of the passes to be turned in a new set of rolls by the roll-turner. As the ironmasters' business gradually increased it was found necessary and more satisfactory in order to obtain greater efficiency to do away with such haphazard methods and to put the responsibility for the proper designing of the rolls into the hands of one man, who became in time a specialist, and was called a roll designer. Thus, very large mills employ a roll designer —who is also a roll turner of wide experience, and who does nothing else but design rolls for the orders of different shaped sections that are continually being received.

### To Test Ductility

In cases of this kind the actual turning of the rolls from the designs furnished is done by journeymen roll turners who are under the supervision of a foreman roll turner. In small mills employing 150 or more men it is customary for the management to employ one roll turner who is capable of both the designing and turning of rolls. Small mills, as a general rule, only receive an occasional order from outside sources that call for new shapes, so that the workman can easily keep up the supply of freshly-dressed rolls and also do any small amount of designing work that comes along.

In modern rolling mills the roll turner has a well-lighted shop of his own to do the work in. Small mills mostly place the roll lathe in their machine shop amongst the machinists' lathes, which proves to be very good practice, as the power requirements are grouped together; in addition, most machine shops are so designed as to be very well illuminated and also free from mill dust and smoke.

Those who use an occasional black or uncoated sheet of iron or steel for repair work are often at a loss to know whether the metal is composed of iron or steel. For the benefit of such readers who desire to make a test of any sheets which they may have on hand, the following method of testing will prove satisfactory, as wrought iron and steel sheets can be easily distinguished from each other. Proceed as follows: first polish with emery cloth or a file a spot on the metal until it is bright; then place a few drops of nitric acid on the place and leave it alone for a few minutes. The spot will then appear of an ash-grey color on wrought iron, brownish-black on mild steel, and a deep black on cast iron. It can be not only used for testing sheets and bars but also for cast iron, where any doubt exists in regard to the identity of the latter metal. In handling any acid care should be taken not to get any of it upon the hands or clothing as acids are very dangerous to handle.

### Actual Turning of Rolls

To test the ductility or quality of any sheet, bend it back and forth until it breaks in two. If it cracks on the back surface after one or two bends it is not annealed very well. Should the piece of sheet steel withstand many bendings it will be found to be a very tough, fibrous metal. The above is only a rough shop test but it will serve to give an idea of the quality of any sheet when anyone desires to select a tough sheet of metal to be used in emergency repair work or otherwise. The testing of tin and galvanized coatings by bendings is also a very useful kink, as it enables a person to find out if the pickling and cleaning operations have been properly done, which is necessary, as otherwise bending will make the coatings peel off when their adherence to their metal base is slight. In regard to the engine power required to drive sheet mills and plate rolls as contrasted with the power needed to operate rolls for making other sections, it has been found out by experience that engines and electric motors used to drive rolls for manufacturing heavy sheets and plates of all descriptions require to be far more powerful than those needed for making other shapes and sections. This is due to the position of the metal rolled being parallel to the rolls' axes, it exerting a force that is comparable to a powerful brake. For the latter reason large diameters of necks and roll bodies are used in mills of this kind. Large diameter necks in turn also create more friction on the bearings, which, coupled together with the pressure that is exerted by the metal being rolled thus makes more power necessary. To the uninitiated person who looks at any sheet mill crew working rolling either sheets for automobiles or for tin plate, etc., the manufacture of these sheets looks very simple and easy and they haven't the least idea of the trouble that can occur unless the heaters and mill crews work together in harmony and for the general good of all.

**Moving Office.**—The J. A. M. Taylor Machine Tool Supplies has moved from the Stair building, at the corner of Bay and Adelaide streets, Toronto, to new quarters at 77 Adelaide street west.

## THE USE OF PEAT AS FUEL

In a lecture delivered by Professor P. F. Purcell before the Royal Dublin Society and published by the Fuel Research Board, it is stated that the total amount of peat used in Ireland lies between six and eight million tons per annum, as compared with 4¾ million tons of coal imported and 90,000 tons raised in the country. Irish peat has advantages in two respects, (1) the ash content is comparatively low, and (2) the nitrogen content is comparatively high. It is, therefore, a good peat for the recovery of sulphate of ammonia. Peat, generally speaking, contains from 90 to 95 per cent. of water, and part of this moisture cannot be pressed out owing to it being held by the colloidal matter in the peat. There are at present only two installations in Ireland where this fuel has been successfully employed for the generation of power. One is at Clifton, in Galway, where the Marconi Company uses 5,000 to 6,000 tons of air-dried peat to generate the power for the wireless station. The other is at Portadown, where the power for a linen factory is obtained from a producer gas plant using peat as the fuel.

---

We understand that preparations for the British Industries Fair, Birmingham, 1921, which is to be held in the permanent buildings of the Castle Bromwich Aerodrome from February 21st to March 4th next, are now well under way. It will be run under the control of the Board of Trade and the Birmingham Municipality and Chamber of Commerce. None but British and British Empire manufacturing firms will be allowed to exhibit at the fair, and, and none but bona-fide British or foreign buyers may be visitors by invitation of the Board of Trade.

---

In a paper dealing with the uses of aluminium for electric installations, Mr. E. O. Pannell, the author, states that aluminium can be drawn three times as far as copper without having to anneal it. The finished wire should indicate 58 to 62 per cent. of the conductance of copper wire of the same size, but it is usual to take 60 per cent. for this figure and a tensile strength of 24,000 pounds per square inch. Thus, if it is required to replace a copper wire on an overhead line with one of aluminium, the latter must have a 29 per cent. greater diameter and a 66 per cent. greater area. To increase the tensile strength and so permit a reduction in the sag of the conductor between the supports aluminium strands are laid around a core of steel wires. The steel wires are double galvanized and impregnated with fish oil to prevent corrosion. A cable of this type is about 35 per cent. heavier than aluminium, and costs, it is stated, 4 to 5 per cent. more; but it has a sag on long spans of 50 per cent. less, so that especially high towers are obviated.

# Special Two Spindle Semi-Automatic Miller

## A Machine Made for a Special Purpose, viz., to Mill Transmission Covers—Two Covers are Milled at One Setting—Special Locking Devices are Used

By J. H. MOORE

THE TWO Spindle Semi-Automatic Horizontal Miller described herein, is a new departure in shop equipment. Figs. 1 and 2 illustrate two different views of this machine, and the Ford-Smith Machine Co., Ltd., Hamilton, Canada, who are the designers and manufacturers of this Miller, have given us some interesting data regarding the same.

The machine was made for one of the large motor companies to mill their transmission covers on a new self-starter engine. Two of these covers are shown on the table of machine at Fig. 2. These covers are so designed that there are two parallel faces, one slightly ahead of the other, to be milled. In order to procure maximum production the special machine was designed. This machine is milling during a very large proportion of its running time, as the operator clamps one cover on the turntable while the other is being milled. An automatic rapid power traverse to the turntable is also provided, and it is largely by these features that such a large production is maintained.

The machine is of exceptional rugged design, and the location of both spindles can be clearly noted at Fig. 1. A feature of the design was the adoption of standard parts as far as possible, that is, the parts going to make up the regular type of Ford-Smith Miller.

The column is practically a duplicate of their heavy model standard type, but shortened to bring the turntable top to the most convenient height for the operator. Fig. 3 illustrates clearly some interesting features in the machine, and for reference purposes we will speak of the parts by symbol numbers as marked on the line drawing.

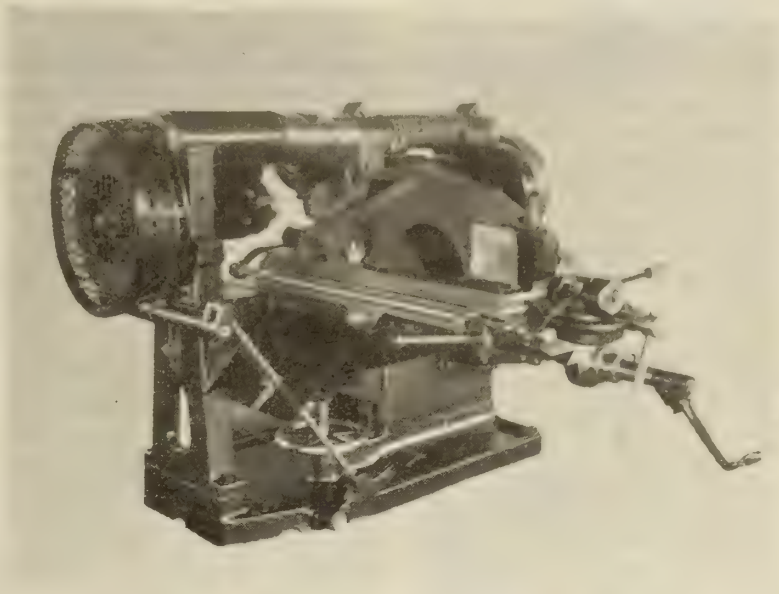

FIG. 2 THIS VIEW SHOWS BOTH COVERS IN POSITION, WITH TABLE BACK FROM THE SPINDLE.

The surfaces that are to be milled can be seen clearly on the outline drawing of the parts. Two castings are placed on the turntable at once, and held down by special bolts and clamps, see 19 AM 27. The turntable is pivoted in the center, and revolves on the stud 8 AM20. Wear on this swivel stud can be taken up by means of the conical sleeve No. 9 AM20, and split outer ring No. 10 AM20.

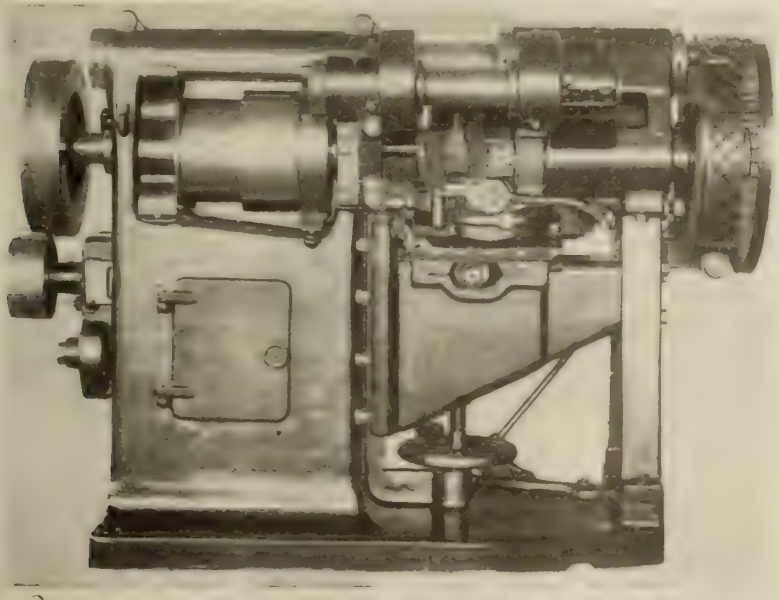

FIG. 1—GENERAL VIEW OF THE SPECIAL MACHINE.

The method of locking the table in position is well worthy of note. Two locating plugs for engaging the turntable edge are employed and these are not entirely dependent upon springs. The locating plugs No. 2 AM17 are made of tool steel hardened and tapered where they engage with the hardened tool steel blocks No. 33 AM27 set in the turntable. The plug nearest the cutter, and consequently the most important one is positively pulled into engagement with its notch by means of the side locking cam No. 37 AM27. This, of course, prevents any radial play.

To revolve the turntable a pull on the handle No. 2 AM13 releases both plugs, as the handle just referred to operates in turn the rod No. 11 AM17, and the lever No. 4 AM13. In this way both plugs are controlled from one handle.

The method of clamping turntable rigidly, after it has been located, is also worth mentioning. This is accomplished by means of two floating clamps, No. 1 AM21 and No. 2 AM21. Both these clamps are operated from one handle in front of machine. This handle is shown at No. 8 AM17. These clamps float and the holding down grip is equalized on all four corners. The tension rod No. 7 AM17 equalizes the pressure by connecting the front and rear clamps. A good powerful grip is obtained and no movement of the turntable is possible.

When it is desired to leave the turntable in an unlocked position, while swinging the same, the little latch is

turned a half turn and engages with the pin shown in lower view. Another feature in this machine is that the outer cutter head can be adjusted along the overarm in thousandths by means of a thread on the arm, together with suitable lock nuts. To take care of wear in the cutter a fine adjustment is provided on the cross table by screw No. 16 AM17. On making the necessary adjustment on the main spindle cutter the outer cutter head is likewise adjusted to suit the amount moved. The method of bracing the overarm and base is so self-apparent that no mention need be made except that slotted holes are placed in outer cutter head to allow for adjustment.

To prevent the workman getting hit by revolving handle of table a special safety handle No. 13 AM13 is provided. This handle is so constructed that when the hand is removed the handle itself is kicked out of position by the pin and spring No. 17 AM27. No danger can follow as the handle cannot revolve, but hangs down idle.

Fig. 2 shows the machine provided with a brake lever. A metal band goes around the enclosed flywheel, and the operator after shutting off his power can soon stop the machine by stepping on the treadle. Vertical adjustment to the knee is obtained by means of handwheel shown.

The object in having two flywheels on the machine was to eliminate as far as possible all vibrations at the cutters, and the installation of these wheels has proved worth while as they accomplish perfectly the duty alloted them. As the material milled in this case is dry, no pump system is required.

The feed box and rapid power box is driven from the countershaft and not from the main spindle, as is usually the case. In this way the rapid power can be engaged for returning the table with the spindle stopped. The inner side of the table is provided with three stops. The end stop trips the feed when the cut is finished. The middle stop automatically engages the feed at the right place when the table is moving in quickly under the rapid power. The outer end stop trips the rapid power when the table is returned after cut is completed. Push knobs are provided, making these various motions self selective, thus avoiding chances of damage to the mechanism.

The faces being milled on this work are approximately 4¾ x 4½″ and a surface is milled at bottom of boss as well as on the side. From 1-32″ to 5-32″ of cast iron is removed, depending upon the castings, and a feed of 4″ per minute is used. Roughly speaking, 160 of these covers are completed every eight hours. Results with this machine have proven that it pays, when necessary, to make special equipment for such duplicate type of work.

---

There are various methods of preserving timber, and some of these were given recently in the Building Age. They comment as follows: The steeping process consists merely in soaking the timber in a water solution of a preservative. The wood must be thoroughly seasoned and left in the solution one day for each inch in thickness and one additional day. After treatment, the timber should be air-dried before using. Zinc chloride attacks lead paints, but is very desirable otherwise. Mercuric chloride is very effective, but is poisonous and has a decided corrosive action on steels. Sodium fluoride does not attack paint, is not corrosive, and in most other respects is very desirable. Timbers may be coated with coal tar creosote by a brush treatment, by dipping in hot oil for five to fifteen minutes, or by the hot and cold bath method. This method consists in submerging the lumber in hot oil for several hours and then either allowing the oil to cool down slowly with the wood in it or plunging the wood into cool oil and leaving it for several hours. Coal tar creosote is objected to by some insurance companies, but whether or not it really does add greatly to the inflammability of wood is a debatable question.

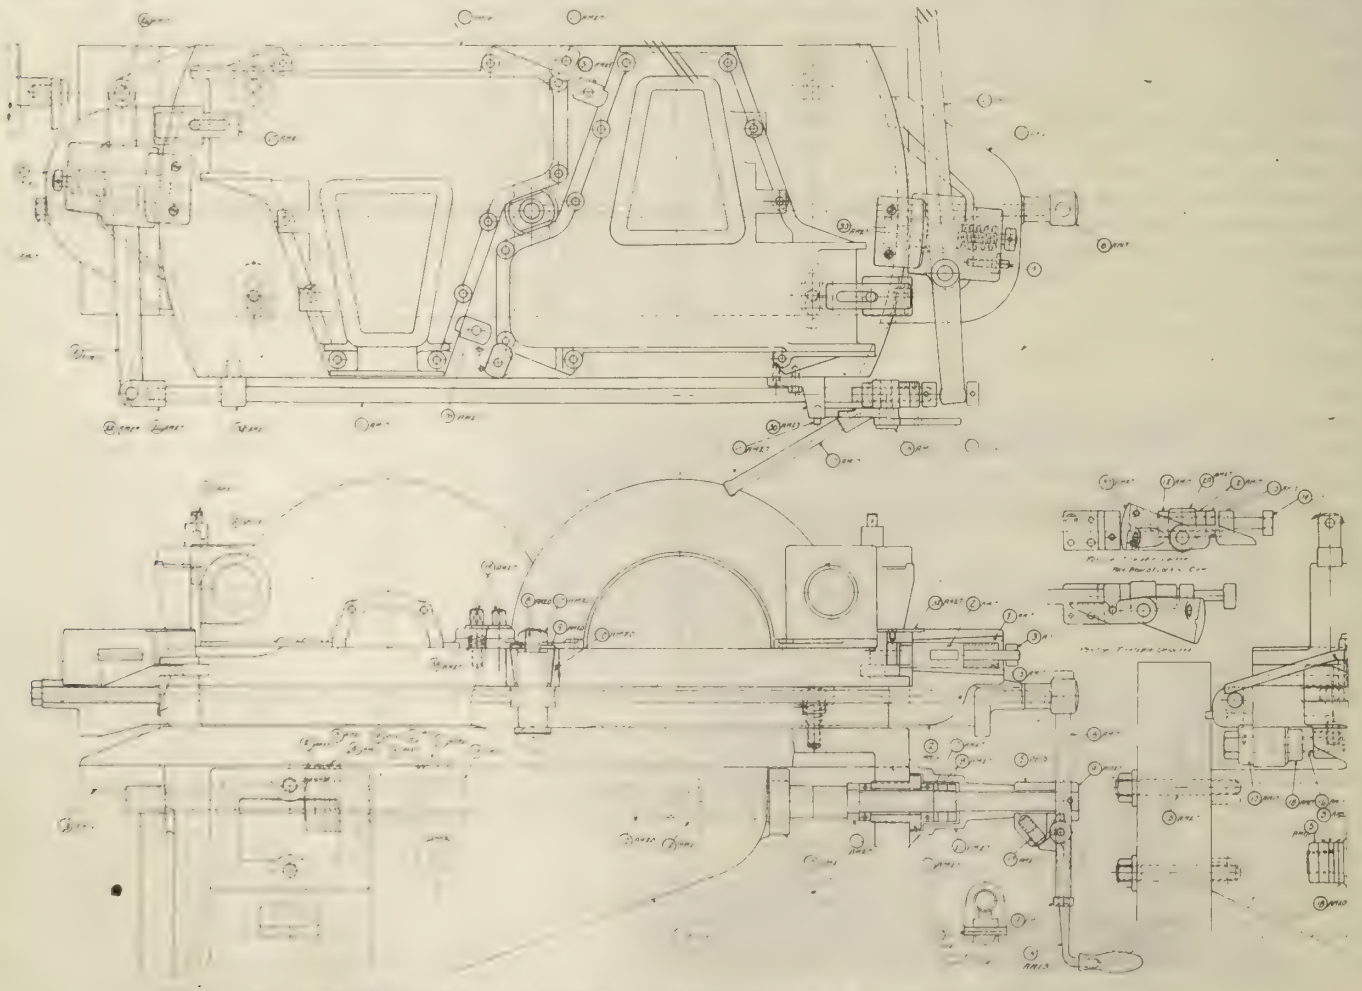

FIG. 3—THIS PARTIALLY SECTIONAL VIEW ILLUSTRATES VARIOUS FEATURES. REFER TO THE TEXT MATTER FOR DESCRIPTION.

# WHAT OUR READERS THINK AND DO

## DRILLING JIG WITH FLOATING CLAMP BAR

John S. Watts

The drilling operation on the link shown in Fig. 1 presents a rather interesting problem by reason of the location of the holes, having to be in correct relation to three surfaces. The link is a steel casting for a picking belt, which is virtually a steel plate conveyor. The plates are five feet wide and have each a pair of links riveted to them so as to form two complete chains, one at each side of the conveyor. There are two sprockets on the driving shaft, with teeth to take the links, these teeth meshing with the links at the point marked "a."

The plate is shown dotted in Fig. 1, and it will be noticed that it projects at one end to lap over the preceding plate, to prevent any leakage of coal.

The holes for the rivets connecting the plate to the link are cored, the only machine work being the drilling of the pin holes. From the above it will be seen that the requirements are as follows:

First, the centre lines of the holes must be square with a line drawn through the centres of the double eye and single eye.

Second, in order that the plates will mesh correctly, the pin holes must be drilled at the correct distances from the surfaces of the pad "b," to which the plate is to be riveted.

Third, to ensure that each of the two links on a plate will mesh with the two sprockets correctly, the two pin holes must be the correct distance from point "a."

In Fig. 2 is shown the jig, and we will show how each of the above requirements have been met.

In designing the jig to fulfill the first requirement we must remember that the link is not to be machined and that therefore the actual dimensions of the castings will be apt to vary slightly from the drawing sizes. For this reason the width of the space between the jaws of the double eye of the link is ⅛ of an inch greater than the width of the single eye.

The spaces in the jig into which the double eye and single eye fit, respectively, must be greater than the widths of these parts of the casting as given by the drawing. The clearances should be one-sixteenth to ensure that any casting that will go into the jig will also fit into its place in the chain. For instance, the maximum over-size the jig will admit on the single-eye is one-sixteenth and the maximum under-size on the space between the jaws of the double-eye is also one-sixteenth, and as the drawing gives one-eighth clearance, the maximum width of single eye will just go into the minimum width of space in the double eye.

When the link is placed in the jig it rests on one face of the single eye and an inside face of the double-eye, and as any over-size in the casting will probably be equal at both places, the centre line of the link will lie in a horizontal plane. In any case we are assured that any link that will enter the jig will fit the other links, and that at least two of the faces of the bosses are in their correct location and will be as good a job as can be gotten with rough castings.

The second and third requirements must be studied together and in the jig shown this is accomplished by having the casting clamped against two surfaces, one of which controls the location of the surface "a" and the other that of "b." When the casting is being entered into the jig, the clamp is swung out on its hinge and the casting pushed into place, the clamp swinging in as the casting enters the jig. Tightening up the thumb screw causes the clamp, first, to push against the end of the link and so press the point "a" against the stop in the jig provided to locate this point, and then, secondly, to force the link into the jig until the pad "b" is against the surface of the jig at the back, which locates the position of the pad in reference to the holes. As will be seen, we now have the casting clamped in the jig in the position desired to fulfill the three requirements enumerated above.

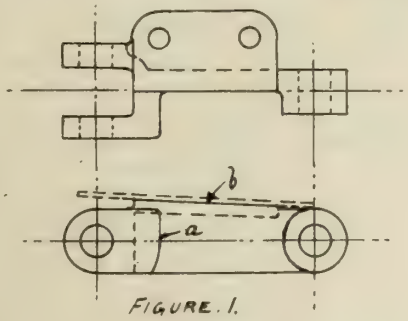

FIGURE 1.

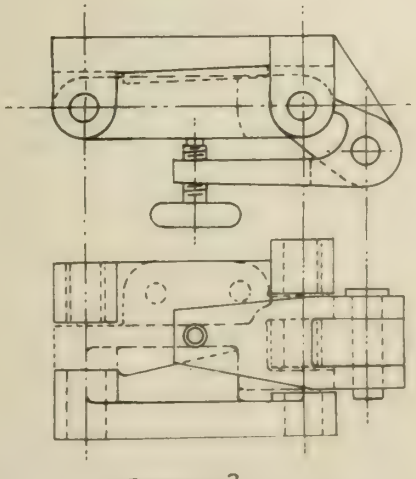

FIGURE 2

FIGS. 1 AND 2—ILLUSTRATING THE PART ITSELF, AND THE JIG.

This would not be possible of attainment by the use of a single clamp, as there would be no assurance that surface "a" would be correctly located. To depend upon the operator pressing the casting against the stop is to depend upon "a broken reed." And if two clamp screws were fitted, the casting would be easily placed wrong by tightening up the wrong clamp first. Then also the operation would consume more time than that required using the jig shown.

To remove the casting from the jig it is only necessary to slack up the thumb screw a few turns, when the link can be withdrawn, as the clamp swings out of the way as the link comes out.

---

Creosoted wood cannot be painted over successfully, because the oil quickly comes through the paint and discolors it. Although pressure treatments are the most expensive they are the most effective because they result in the greatest absorption and penetration of preservative. Roof planking should receive 8 lb. to 12 lb. of creosote per cubic foot, or ½ lb. of the salt if zinc chloride be used. Such treatment should add at least twenty years to the life of roof plank. Lumber should be cut to final dimensions before treatment. Whenever it becomes necessary to cut into treated timber the untreated wood exposed by cutting should be given two brush coats of creosote or some other preservative.

# Safeguarding Operation of Industrial Cranes

## Crane Inspection, Safety Devices, Proper Slings, Duties of Operator, Proper Chains to Use for Different Purposes, the Endless Chain Sling, Identification of Chains

By JOHN A. HOPE

THE rules and regulations, herewith set forth, governing the shop maintenance of cranes and hoisting chains, and care of the same, is submitted by the writer, recognizing the importance and considerate attention that has been given to this subject by one of Canada's leading railroad companies, in safeguarding workmen from injury. It is doubtless true that many industrial firms have adopted ways and means for the protection of the workmen that may be similar to those here given, but a brief discussion of some details at this time may prove beneficial to many of the readers.

### Shop Cranes

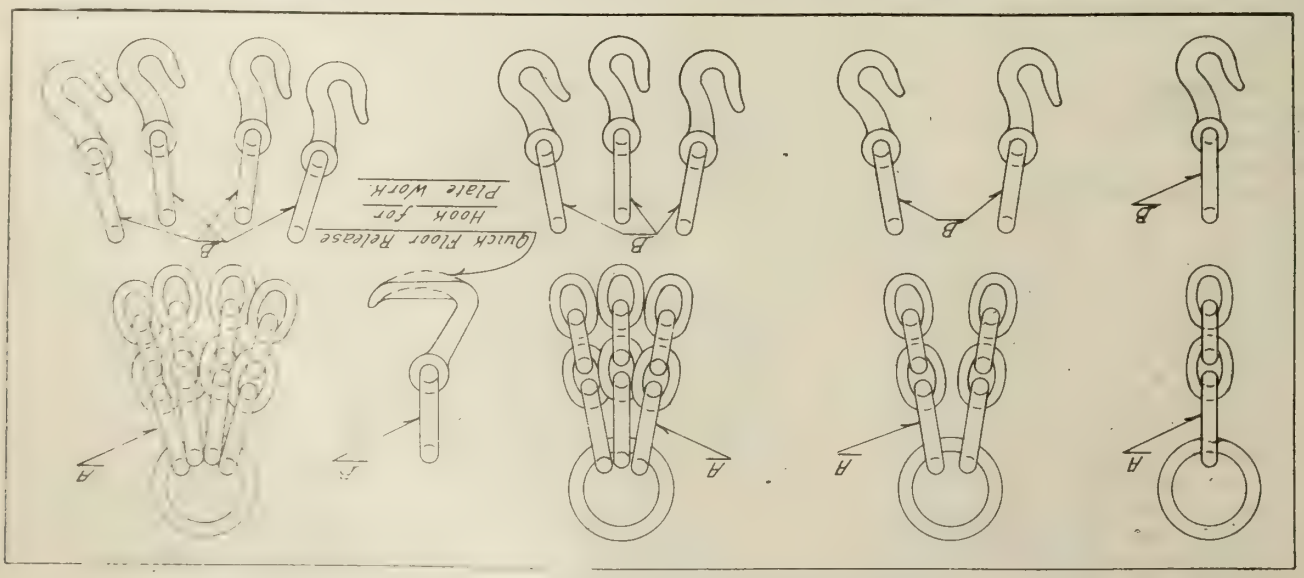
The general construction of modern workshops provide ample overhead room for carrier cranes, and according to the length of the building and the nature of the work, two or more of these cranes may be operating on the one runway, with a minimum tracking height of about 330 feet from the floor. The duties of these cranes involve the rapid transit of shop material from one department to another, where floor conveyances are not convenient. The operators in charge of the cranes are constantly engaged in the different positions below them and seldom are required to watch the movement of the crane along the tracks, and therefore assume that there are no obstructions to the crane tracking when moving along the rails. This makes shop orders effective that no class of workmen, steam fitters, etc., working on maintenance of building, are allowed to work in the vicinity of cranes, except in the case of emergency repairs which must necessitate the stopping of the crane from operating in the section where the trouble may be.

### Crane Indication

It is most advisable that all cranes be painted with a light distinguishable color, to contrast sharply with the building interior and surroundings, so that they will be quite noticeable to all floor men in the works; also that the rated capacity of the crane be stenciled in large lettering on both sides or bridges. This capacity should always read in tons, as men do not grasp the significance of pounds capacity as well as they do tonnage.

### Crane Safety Devices

In order to facilitate repairs, all cranes should be equipped with suitable runways that will provide easy access to carrying transmission, propelling gears, bearings, motors, etc. These runways likewise permit of ready inspection at all times. All overhead crane equipment should be controlled by limit switches for extreme load height; also include the best features in drum clutch and brake devices, automatic gong ringer, etc.



### Crane Inspection

Whether the number of cranes warrant an inspector on the job all of the time or only part of it, it is necessary that cranes receive a close inspection at least once a week. This inspection must include a very careful examination of the hoisting cables, to ascertain that there are no damaged or broken strands, and that cable sheaves are not worn to cause any cable defects. It is possible and expected that a good brand of cable, kept in good condition by frequent oiling and used for moderate lifting within crane capacity, should at least give a satisfactory twelve months' service, that is, for machine shop service; foundry cranes cannot be governed by this rule, on account of the extra usage and the continual dust. However, there is no other interpretation of the shop rule, which states, each or any cable inspected and discovered with broken wire in strand must be immediately discarded and new cable applied, irrespective of what length of service damaged cable has been in use.

As previously stated, cables on general service cranes (excepting founddries) should have a predetermined renewal date set, according to the number of days or hours crane is in use, always taking into consideration the nature of the material handled, for although cables may not show weakness in broken strand wires, the breaking strain may be very materially reduced, with too continued service.

### Crane Operators and Slings

The present practice, where one or more carrier cranes are in continuous use, is to provide a competent slinger, who takes the responsibility of slinging all material to be handled, and in seeing that all material is placed in the proper position. Rules applying to crane operators and slingers are for eliminating any misunderstanding. 1st.—Crane operator being responsible for material load when hoisted, that there is no undue swing to load, and that observance is made to clear projecting wall cranes, etc. 2nd.—That crane operator takes his signals from slinger with respect to hoisting, lowering, or carrying of ma-

A ONE, TWO, THREE AND FOUR-LEG SET OF CHAINS.

terial. 3rd.—That crane operator can refuse to make load lift, if in his estimation improper fastenings or under capacity slings or chains are used by slinger. 4th.—Slinger to be fully competent in the use and capacity selection of chains which are at his disposal and generally indicated for their special use. 5th.—That in handling or placing material in a predetermined position for mechanics involved, all signals must be transmitted through the slinger to the crane operator, for too many signal bosses will tend to create accidents and cause unnecessary confusion. Cordial co-operation is demanded from crane operator and slinger, and where repeated friction is apparent in the handling of material, a change is effected.

### Chains

In the accompanying sketch are shown a set of one, two, three and four leg chains, and these are considered as the most serviceable for all round use in foundry, machine and erecting shop service, not excepting the endless chain sling. These chain lengths are made up of No. 1 best tested, oval link, wrought iron, for hoisting purposes, covering a lifted range from 1-4 to 20 tons, as illustrated. This is in reference to general shop use, as there are a large variety of special chains for work of specific character. With reference to the head ring on these chains they are made a relative size for the different chains, to facilitate hooking on to the carrier crane main hook. Ring thickness is made to suit the chain capacity. Chain data is omitted in this article, as this information may be had from any of the hand-books now available. The safety factor used for hoisting chains approximates 5 to 7, that is, 1-5 to 1-7 the breaking strain of chain being the allowable carrying load.

It is freely conceded that the one and two leg hook chains, and also the endless sling chain, are the most expedient and desirable for handling material in erecting, foundry and structural work. The two, three and four leg chains, with different width hooks, are the best adapted for boiler and tank plate work. The three leg chain is recognized as the safest flat plate carrier on account of its three point suspension, thereby decreasing the possibility of plate slipping.

### Rope Slings

Manila or hemp rope slings are not included in the shop equipment for general sling work, on account of being subject to strand cutting when used on rough or sharp edged material, yet their field of usefulness is so extensive that it is almost essential to provide such slings for specific uses. The 1-inch and 1¼-inch rope slings (endless) are much preferred by erecting millwrights. Light material that is being installed down from large or heavily constructed machinery, necessarily requires a light sling, and where small parts are being handled in a confined space, with the probability of being jammed, the rope is more suitable, as it enables the operator to watch any crowding of the work against adjoining machinery. Light ¼-inch chain slings, where a heavy power crane is doing the work, will not stand up to this momentary strain, and frequently results in a bursted link and falling of material. Rope slings are very serviceable when placing light material inside of locomotive boilers, where view is obstructed.

Tube handling in large quantities give preference to the 2 and 2½-inch diameter endless rope sling, as it has a natural tendency to hug the tubes securely and preventing slipping, and in the case of thin tubes, avoiding damage to the same.

### The Endless Chain Sling

This chain, in ¼ and 5 16 inch open link sizes, ranging from 3 to 5 feet in length, is regarded by machine shop operators as one of the most necessary individual pieces of equipment of any they have got. These chains are used with wall cranes equipped with air hoists or quick-acting chain blocks as lifting mediums, the average weight of material handled being from 100 to 1,000 lbs. Mechanics making daily use of such chains carry their work out in routine manner, so that little thought is given to the possibility of chain breaking and causing injury. The need of regular inspection is therefore obvious. The following is a conversation the writer had recently with a workman using a chain as cited above.

"Where is your chain sling?" Machine operator produces the same. "How long have you been using this chain?" "Possibly five months." "Have you ever examined the individual links in the chain for possible defects?" "Well to be candid—No. I did not." "Don't you think that it would only be fair to yourself to give your chain a two-minute inspection once a week and thereby save yourself from possible injury?" "Well, I know you are right, as I have never given it a thought. I am going to take a squint at that chain right now, for now that I think about it I have made that little old chain do some work this while back." This is not to cast reflection on the ability or carelessness of these men, who just simply acquire a familiarity with their working surroundings and forget to be concerned in matters not dealing directly with the work. To make it a plainer statement, these men are more mindful to the material held in the sling than to the sling itself, which for the common needs of safety, in seeing that chains are kept in good condition.

### Chain Inspection

Inspection of chains requires that an inspector becomes acquainted with the following duties. To inspect daily the condition of chains in the different departments, checking up those that show wear or abuse. Single leg chains checked up for undue stretch by their known length. Two, three or four leg chains are checked up by taking notice, when suspended on crane hook, that no one leg exceeds others in length. Care should be taken in making these chains that all sections are of equal length from the ring head. Where hard usage has caused noticeable dents or bent links, it is necessary that the chain be discarded and a new one applied; the long links as shown in A and B constitute the only part of chain allowed for smith-shop welding. The welding of any other link in chain leg is prohibited as further assurance of safety, not that there should be distrust of the welded link renewal but the general insecurity of other parts of the broken chain which may be strained. By renewing the entire chain leg there is no doubtful action taken.

### Chain Identification

It is part of the chain inspector's duty to know exactly how many chains, and type, are in daily use. This requires that each chain have an identification number stamped on it, this to enable inspector to keep record of their use or abuse. Record of the same to be kept in card index or log book. This identification to read as follows: Number of chain, 50; kind of chain, double (plate hook); length and size, 6 ft. 0 in. x ⅝ link; where used, plate department; when made, 1—8—1918; last annealed, 3—6—1920; remarks, O.K.

### Annealing Chains

The advisable practice is to anneal all chains semi-annually, especially those that are being used in continual and heavy service, as these develop a tendency to become crystallized. The method for this annealing is to put chains in a series of rows on the bed of the annealing furnace, one that is oil fired being preferred. With furnace closed up, gradually apply heat until chains attain a cherry red. Shut off the heat and allow furnace to cool until chains can be removed by hand. The inspector is then called upon to examine chains carefully, link by link, as this annealing invariably shows up seam fractures, that are indiscernible when chains are in use and oil coated. Chains inspected and found O.K. are then oiled. Large chains are brush painted, and the smaller chains dipped in oil tank and then allowed to drain off. They are then returned to their various departments for service.

---

A locomotive turn table, 92 feet long, was recently lifted and moved horizontally 1,600 ft. at Kansas in ten hours by means of a 100-ton wrecking crane and two railway flat trucks. The crane first lifted one end of the turn table and a cribbing was built underneath at about two-thirds of its length from the crane. The crane was then lowered away. This action raised the far end and a cribwork was built there. The crane gave another hoist and the first crib was heightened. By repeating this process the turn table was raised high enough to admit the trucks below far more quickly than could have been done with jacks. Once on the trucks the table was easily hauled by a locomotive to its new site.

# DEVELOPMENTS IN SHOP EQUIPMENT

## UTILITY SCREW PRESS

Carl Pletz & Sons, 717 Sycamore St., Cincinnati, Ohio, have placed on the market what is known as their No. 3 and No. 3½ utility screw presses. The illustration depicts the press, and, as stated, it is made in two sizes. This type machine is used to straighten shafts, bars, rails, beams, etc. It is also arranged to press in or out bushing, press gears or wheels on and off shafts and can form or bend metal in many shapes.

The bed is 4 ft. long, deep and heavily ribbed with a hole cored under the screw to permit work to drop through to the floor when pressed out. These cored holes permit the pressing of pieces in or off of long shafts. The two upright posts are strong enough to withstand ten times the load that can ever be applied.

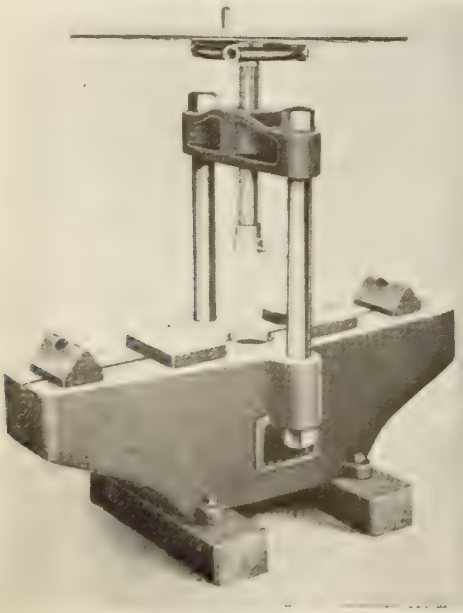
The screw is made of high grade steel accurately chased. The steel screw pad fits on the end of the screw and the thrust is taken on a hardened steel and bronze washer, which is set in oil.

The hand wheel on the end of the screw is fitted with a handle so that the screw can be returned quickly. By using a four-foot bar in the hand wheel a pressure of about 20 tons can be secured. Following are the principal specifications:

| | No. 3 | No. 3½ |
|---|---|---|
| Size of screw | 2″ | 2″ |
| Pitch of screw | ¼″ | ¼″ |
| Distance between posts | 12¾″ | 17¼″ |
| Distance under screw pad | 14″ | 20″ |
| Length over all | 4′ | 4′ |
| Height with screw down | 42″ | 42″ |
| Weight | 500 lbs. | 600 lbs. |

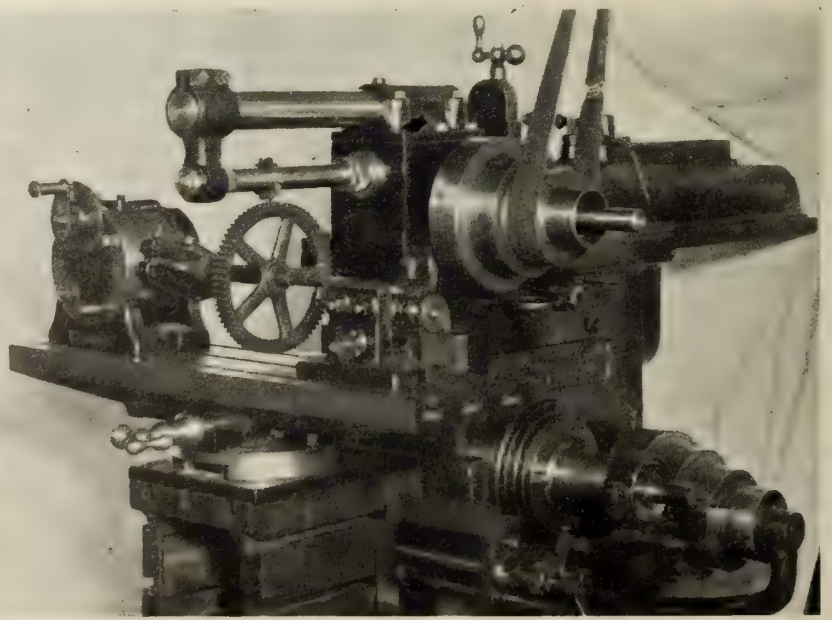
## SHAPER MILLING ATTACHMENT

The Tri-State Milling Machine Co., 172-174 South Front Street, Memphis, Tenn., have placed on the market a milling machine attachment for use on shapers. This attachment is shown on the photograph, and the makers claim that this fixture is good for the following uses.



The attachments are made to fit any size or make of shaper, and in very short order the shaper is transformed into a miller by use of this fixture. The attachment is used to cut spur gears up to 18 inches diameter, also bevel and mitre gears, worm gears, keyseating shafts almost any size with one cut, woodruff keyseating, plain slab milling and form milling such as forming and shaping up dies and punches, profile work such as milling out circular slots, fluting reamers, taps, or similar work. This is said to be a powerful attachment because it is worm driven by a triple cut worm and gear, running in a closed gear box filled with heavy oil, which lubricates every bearing from the inside of the gear box; all bearings are taper and provided with a lock nut, one on the inside and one on the outside for taking up the wear.

Following are the principal specifications: Milling head—Cast iron, heavily constructed, fitted for ram slide and fastened with gib key. Pulley—four step cone, 4, 6, 8 and 10 inch, 2½ inch face. Bearings—bronze, taper adjustable for wear. Drive—worm and gear, hardened steel, runs in oil. Drive shaft—nickel steel, hardened steel thrust bearings on each side of worm. Runs either right or left. Spindle—Hollow high carbon steel; 1⅞ inch diameter. No. 4 standard Morse taper. Nose threaded for chuck. Arbor—Nickel steel, 1 inch diameter. Only one furnished. Table—3 feet long, 3 T-slots, round base permitting turn at any angle, cross feed 7 inches. Table fits on shaper base, giving quick adjustment.

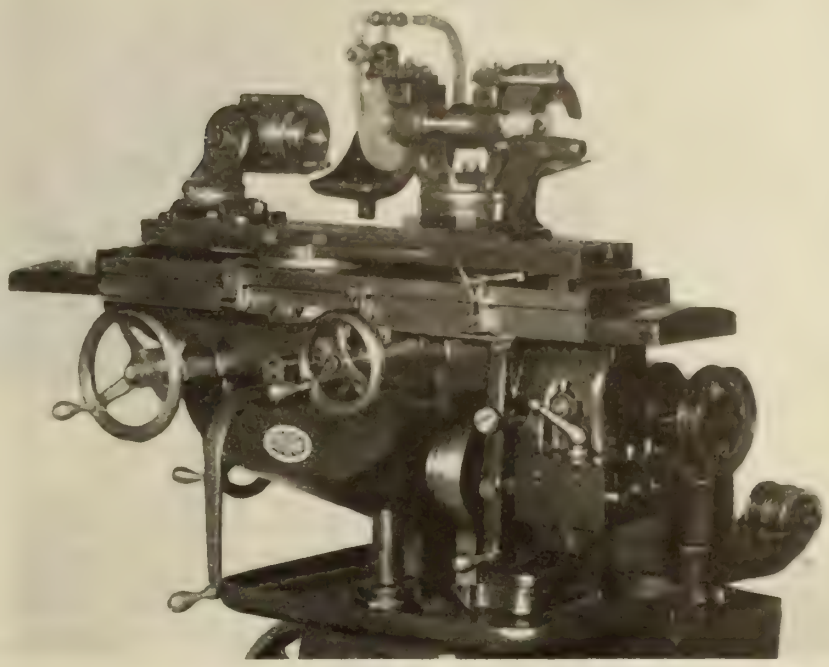


## FRICTIONLESS CENTRE

The Snellex Manufacturing Co., Rochester, N.Y., have placed on the market what they claim is a frictionless centre.

This centre is designed to eliminate friction between the work and the centre, to make it unnecessary to regrind centres, to increase production at a

UTILITY SCREW PRESS.



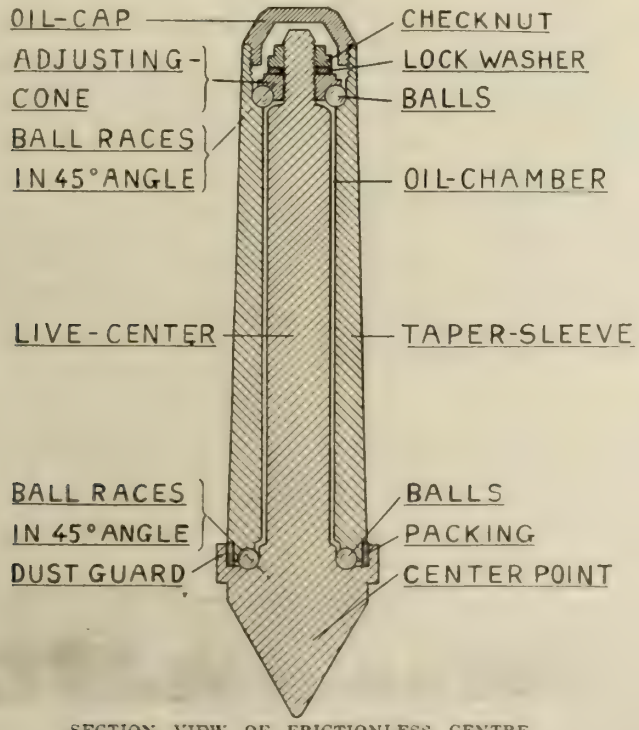
SHAPER MILLING ATTACHMENT

higher speed, and to prevent worn or burnt centre holes in the work. It is also said to do away with the unsatisfactory lubrication between centre and work. The arrangement of the ball-bearings and the general construction is plainly seen in the accompanying sectional view.

The live centre is mounted in special ball bearings, at the rear end of the centre is an adjustable cone, together with a lock washer and check nut, and the end is sealed with an oil cap. The principal point of novelty lies in the construction of the ball races, which are the peculiar movement of the balls, formed at an angle of forty-five degrees.

This arrangement has the following advantages. It insures the greatest sensibility of the live centre without end or side play, and a permanent trueness of the balls to one ten-thousandth of an inch. This last feature has its secret in which are travelling in a spiral motion caused by the forty-five degree angle of the races. This insures a perfect and uniform wear of the balls which keeps them round and true in size. These centres are made in four sizes, varying from No. 1 to No. 4 Morse taper.

GENERAL VIEW OF THE GRINDER.



## UNIVERSAL TOOL ROOM GRINDER

The Oakley Machine Tool Co., Cincinnati, Ohio, have placed on the market their No. 3 universal tool room grinder. This machine has incorporated in it certain features intended to insure, during the life of the machine and under all working conditions, accuracy, rigidity, and convenience of control. The longitudinal feed may either be hand-operated or driven by power. The fast hand feed is operated through a rack and pinion, either from the front or rear of the machine by a long hand-lever. A small handwheel in front of the saddle controls the slow hand-feeding movement. The power feed is driven by a single belt from a countershaft, and constant belt tension is maintained irrespective of the position of the knee. There are three feed changes obtained through a cone pulley.

The operating and reverse levers are directly under the operator's hand. Hardened chrome-nickel steel is used for all reverse mechanism clutches. The cross-feed is operated by a large diameter handwheel, either from the front or rear of the machine, and there are micrometer dials at both ends of the cross-feed screw. Another large handwheel is used for the vertical feed, which has a micrometer dial on the elevating shaft. The thrust is taken by ball bearings.

The slide of the machine is aligned to the saddle by vee and flat bearings of liberal dimensions. This slide is designed to maintain true alignment during the life of the machine, and it is easily removed from the saddle for cleaning. The saddle and knee have V-bearings; and in the case of the slide, saddle, and knee there are no gibs or adjustments for the operator to tamper with. The entire slide bearings are oiled through one centralized oil-cup. The wheel-head swivels on the column 180 degrees either side of the central position. The wheel-spindle runs in dustproof, taper, bronze bearings. The work-head has a No. 12 B. & S. taper for receiving the shanks of large end-mills. This work-head swivels in horizontal and vertical planes.

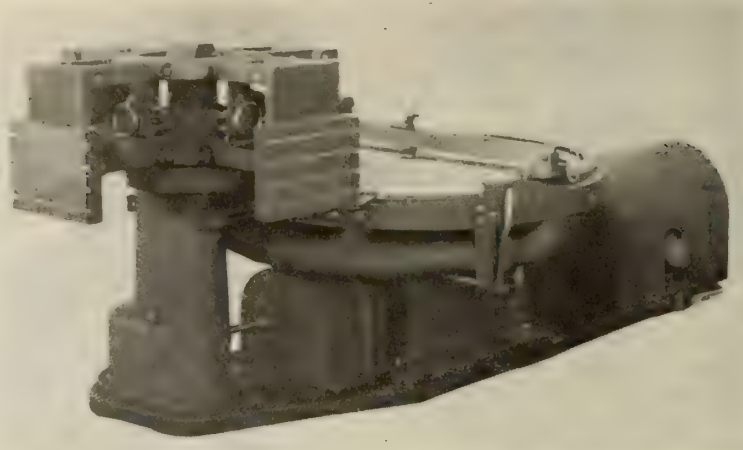
The range of the machine is as follows: Longitudinal movement, 17 inches; vertical movement, 10½ inches; cross movement, 9 inches; maximum swing, 10 inches; maximum distance between centers, 20 inches. The table surface is 5¾ inches wide, and 33¾ inches long. The automatic feeds are 6½ inches, 11⅜ inches, and 19½ inches per minute.

SECTION VIEW OF FRICTIONLESS CENTRE.

## CONTINUOUS FEED DISK GRINDER

The Gardiner Machine Co., Beloit, Wis., have recently placed on the market what is known as their continuous feed disk grinder. This machine is semi-automatic in operation and is designed to eliminate the usual amount of

labor expended in operating hand disk grinders. An important feature of this machine is the constant production obtained. With any hand operated machine, the human element has to be considered and naturally a uniform output cannot be obtained.



The machine carries a horizontal disk wheel 53" in diameter, and is provided with a revolving reel, which carries four work tables, as shown in illustration.

The work to be ground is attached to these tables by means of suitable fixtures mounted on them, and the revolving reel brings it over the surface of the grinding wheel. The tables are automatically lowered on the wheel. Pressure to insure quick removal of stock is secured through gravity, but by means of a compression spring this pressure may be adjusted. The weight of the table insures application of uniform pressure, which can be increased by adding extra weight if the character of the work necessitates it. A micrometer stop screw makes it possible to remove stock to definite dimensions.

Due to the construction just described, the operator simply places the work in the fixture and removes it when finished. The revolving reel is mounted on a vertical shaft 3½ inches in diameter, and is driven through worm, spur, and bevel gears from the gear driving the main spindle of the machine. By means of change-gears, the reel may be made to revolve ¼, ½ or 1 revolution per minute, thereby producing 1, 2, or 4 finished pieces per minute. Other speeds may be obtained by substituting special gears.

The driving shaft is provided with a friction clutch which is operated by a lever placed in a convenient position, which makes it possible to start or stop the feeding mechanism independently of the grinding wheel. The reel and the shaft which drives it are mounted in bronze bearings; all other shafts are carried in ball bearings. The gears are totally enclosed, which protects them from dust and dirt and allows them to be amply lubricated. The feeding stand is bolted directly to the baseplate upon which the machine is mounted, and to accommodate various sizes of work, has an adjustment of 6 inches along this baseplate. Because the work-tables are at right angles to the grinding heel, accuracy of the work being grouped is assured.

Rigidity and strength are important features of this machine. It weighs about 7,600 pounds when crated for domestic shipment. The disk wheel is mounted on an extra large and heavy cast-iron flange. The driving spindle is of large diameter and runs in two self-aligning radial ball bearings. All down or end thrust is taken on a self-aligning ball thrust bearing which contains ten 1¼-inch diameter balls. Power is transmitted to the disk wheel by hardened special steel bevel gears. The ratio between the driving shaft gear and the spindle pinion is 2.4 to 1. These gears are also fully enclosed within the base of the machine, and provision is made for ample lubrication. They are completely protected from any grit or dust.

GENERAL VIEW OF THE CONTINUOUS FEED DISC GRINDER.

An extra pulley is mounted on the driving shaft for belting to an exhaust fan, which is set on the floor in back of machine. There is a dust channel cast into the base of the machine extending entirely around and underneath the outer edge of the disk wheel. When the guard ring is removed this channel is uncovered all the way around so that the grindings which might interfere with effective exhausting may be removed readily. A dust exhaust manifold is fastened into the bottom of this dust channel in four places and connected to an extra large exhauster, reducing the dust problem to a minimum. The cast-iron guard ring is fastened to the top of the base with collar head screws. Any portion of the guard ring is removable, permitting the grinding of work carrying a lug projecting above the plane of the ground surface.

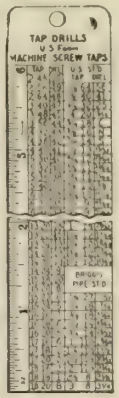
# NEW THINGS IN MACHINE TOOLS

## PORTABLE AIR COMPRESSOR

The Black and Decker Manufacturing Company of Baltimore, Md., are now making a portable electric air compressor outfit mounted on a three-wheel carriage fitted with a pushing handle and brake. Automatic control of the supply is provided for as the machine starts to operate when the pressure falls to 160 lbs. and stops when the pressure has been raised to 200 lbs. per sq. in. A reducing valve is fitted to the reservoir to give a working pressure of from 40 to 80 lbs. The regular equipment includes valves, gages, electric cord, 25 feet of air hose and blow gun. Additional equipment may be supplied if desired.

## MOTOR-DRIVEN TOOL GRINDER

The United States Tool Company of Cincinnati are now making a self-contained tool grinding machine operated by a 5 h.p. shunt-wound, adjustable speed Westinghouse motor running at from 1120 to 1600 r.p.m. The motor is fitted direct to the drive shaft and may be started or stopped by pushing a button, the starter being located in the base of the machine. The control buttons are located on the top of the machine so as to eliminate the possibility of the workmen striking it while operating on the work.



## MULTIPLE-SPINDLE DRILL HEAD

A new design of adjustable-center multiple-spindle drill head has recently been placed on the market by the United States Drill Head Company of Cincinnati. When using six spindles or less, the full adjustability of the head may be obtained, although more than six spindles may be applied but with a lesser range of adjustment. Each spindle is carried on a separate auxiliary arm that may be swung in a complete circle about an intermediate pinion that meshes with the main gear in the central drive spindle. The intermediate pinions are made with a wide face to permit of vertical adjustment to the separate spindles when it is desired to use drills of different lengths. One locking nut is used for holding the spindles in position and any of the spindles may be readily attached or removed. The auxiliary spindles are fitted with ball thrust bearings and are provided with means for adjustment for wear. Five standard sizes are made with a range for drilling on circles from 2 inches to 18 inches in diameter. Special sizes may be had if required.

# Have You Tried This Contest Yet? If not--- Do so Now

Do you want to win one of these scales?

It's very easy, and at the same time you add to your store of knowledge. The details are given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

## What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

The Prize Winner for Dec. 9th Issue is GEORGE LAND, 567 Patterson St., Peterboro, Ont. Another chap from Welland had his answers correct, but was 7 days later than the winner in sending them in.

**CONTEST FOR JAN. 6TH ISSUE**

**Contestants are required to write us, stating to which advertisements we refer in this number.**

1—Something you can't afford to take chances on.
2—How to prevent a certain article from freezing.
3—Something that is solid—yet adjustable.
4—How to eliminate the danger of error.
5—Something that you can accomplish in three minutes.
6—How to reduce non-productive time.
7—How to save money.
8—How to obtain dependable production.
9—Something said to be very popular.
10—How to get away from experimenting.
11—How to get more speed.
12—How to make one pound of one material equal ten pounds of another.

**These are Correct Answers for List from Dec. 9th Issue:**

1—John Bertram & Sons, Ltd.
2—The Wallace Barnes Co.
3—The Galt Machine Screw Co.
4—The City of St. Johns.
5—Dominion Forge & Stamping Co., Ltd.
6—The Bristol Co.
7—Gooley & Edlund, Inc.
8—Nova Scotia Steel & Coal Co., Ltd.
9—Puro Sanitary Drinking Fountain Co.
10—Hoyt Metal Co.
11—A. R. Williams Machinery Co.
12—Norton Company of Canada.

# Machine Tool Designers Were Busy in 1920

## Automatic Turning Machine, Boring Mill, Pneumatic Motor Hoists, Electric Riveting Machine, Blasting Machine, Keyseating Machine, Twist Drill Grinder, and Other Tools Are Included

**The Oliver Machinery Company, Grand Rapids, Mich.**—An improved patternmakers' and general woodworker's vise. The vise is patented and is very versatile in its adaptation to the general line of work found in woodworking departments.

**Manning Maxwell & Moore, Inc., New York.**—A special vise in which three jaws can be swivelled independently, and can be locked in any desired position.

**Alfred Herbert, Ltd., Coventry, Eng.**—This concern has brought out various new developments, but perhaps the three most distinctive are as follows: An automatic turning machine in which there is no overhead gear. The range of speed is obtained automatically, and a new method is used to move the turret. A patent cold sawing machine. This machine has a patent chip remover which greatly reduces the risk of saw breakage and permits of higher speeds and feeds. A radial drilling machine. This machine is just entering on the market and was recently shewn at the Olympia Exhibition in London.

**A. T. Brush Tool Co., Erie, Pa.**—A micrometer that can be used for measuring from zero to two inches without any attachment. The spindle has a screw of 220 threads per inch, while a separate screw with forty threads per inch is used for traversing the spindle.

**National Acme Co., Cleveland, Ohio.**—An automatic machine constructed on the multiple spindle principle. This machine has a capacity of from 3 to 4 inches.

**The Wetmore Reamer Co., Milwaukee, Wis.**—A special set of reamer tools designed for the production of round, straight, and thoroughly smooth holes in small cylinders.

**The Storm Manufacturing Co., Minneapolis, Minn.**—A boring mill that is especially adapted for the boring or reboring of motor cylinders and other parts such as large gears, heavy bushings, tractor wheels, etc.

**Independent Pneumatic Tool Co., Chicago, Ill.**—Various developments have been brought out, these including pneumatic motor hoists, a moisture separator, a power screw driver attachment, a pistol grip electric drill, a hose coupling and a drill repair vise.

**The Kent Machine Co., Kent, Ohio.**—A compound mixture for mixing bone meal and various compounds for pack hardening and carburizing steel.

**The Cincinnati Electrical Tool Co., Cincinnati, Ohio.**—A combination bench drilling stand that has a portable electric hand drill attached.

**Mada Engineering Co., Liverpool, Eng.**—An electric riveting machine which is portable in nature and can be used on outside jobs.

**H. B. Underwood Corporation Philadelphia, Pa.** — A small engine that may be operated either by steam or air for driving portable mechanism such as boring bars and drilling machines. These engines are made in two sizes, two or three horse-power.

**Long & Allstatter, Hamilton, Ohio.**—An improved design of helve hammer of the rubber cushioned type.

**The Victor Tool Comp., Waynesboro, Pa.**—A collapsible taper cutting pipe tap. Sizes of these taps range from 2 to 12 inches.

**The Gray Machine Tool Co., Buffalo.**—A blasting machine that is adapted for the cleaning of the insides of pistons.

**The Bear Pneumatic Tool Co., Kansas City, Mo.** — A pneumatic riveter that is supported on a stand, and is intended for use in riveting traction plates on the rims of pneumatic tires. With slight modification, it can be adopted on a great variety of work.

**Grimscom-Russell Co., New York.**—A multiwhirl oil cooler that is used for the cooling of oil in turbine bearings, reduction gears, or quenching oil used in heat treatment.

**Ackland Specialty Co., Springfield, Mass.**—A screw driver which it is claimed will remove any rusted screw which could not be budged by an ordinary driver.

**The Baird Pneumatic Tool Co., Kansas City.**—An arch flue and pipe bender that is adapted for bending into difficult shapes, locomotive or marine arch flues, also airtight connections used under regular freight or passenger cars.

**The Mattison Machine Works, Rockford, Ill.** — An automatic stroke belt sander. This machine automatically moves the sand belt across the surface.

**Hercules Manufacturing Co., Portland, Oregon.** — A horizontal key seating machine in which the work holding face plate is secured to one end of the machine, and may be tilted to accommodate pieces with tapered keyways.

**The R. S. Whitney Co., Lewiston, Maine.** — A safety repair jack which is designed to meet all classes of car, truck, and tractor repair work.

**Carl Pletz & Sons, Cincinnati, Ohio.** — A screw press that is adapted for the straightening of shafts, bending bars or shapes, pressing in bushings, etc.

**Universal Boring Machine Co., Hudson, Mass.** — A special lubrication system has been arranged for on all machines turned out by this company.

**The National Engineering Co., Sarnia, Ont.** — A line of tool stands, racks, and stools especially adapted for all types of manufacturing plants.

**The Aetna Foundry and Machine Co., Warren, Ohio.**—A machine designed for use in tinning heavy sheets used in the manufacture of milk can bodies.

**The Logansport Machine Co., Logansport.**—A new line of air chucks with duplex control mechanism.

**The Superior Collett Chuck Company, Grand Rapids.**—A new type of collett chuck for drilling machines.

**The Eastern Tube & Tool Co., Brooklyn, N.Y.** — A new line of machine centre points made of high speed steel for insertion in any mild steel shank.

**The Ryerson-Conradson Co., Chicago, Ill.** — A vertical attachment of the semi-universal type. This attachment can be fitted to the ways of the millers. A universal dividing head is also part of their new developments.

**Square D. Co., Detroit.**—A lever safety attachment for side presses. This device is arranged to protect the hands of the operator. The press throws a clutch which brings down a shield, thus protecting the operator.

**Canadian Desmond Stephan Mfg. Co., Hamilton.** — This concern produces a full line of emery wheel dressing tools. They also handle industrial diamonds.

**Bellevue Industrial Furnace Co., Detroit, Mich.** — A semi-automatic twist drill grinder which is arranged for two, three, and four-lip right and left hand drills.

**The Standard Meter Co., Ltd., Toronto, Can.** — Two different types of coal oil lamps that are used for brazing and other kindred jobs. These lamps are said to be both wind and rain proof.

**Augustine-Bacon Manufacturing Co., Kansas City, Mo.**—A reversible driving chuck that is said to grip the stock when running in either direction.

**D. F. Dunham, Los Angeles, Cal.**—A valve grinder is so arranged that a valve face can be ground accurately, even should the valve centre be mutilated.

**J. H. Williams & Co., Brooklyn, N. Y.**—A new line of

Falcon wrench that has a wide range of applications and is particularly adapted for piping installation.

**S. P. Rockwell, Syracuse, N.Y.**— Hardness tester. Machine consists of cast frame and plunger. A vertical, movable chuck holds the piece to be tested. Piece to be tested is raised until coming in contact with testing point.

**The Ingersoll-Rand Co., Sherbrooke, Que.** — Several new tools have been added to their pneumatic lines, these to be known as "Little David" tools.

**The Lovejoy Tool Co., Inc., Springfield, Vt.**—A new line of turret tool holders.

**The Graphoscope Development Co., New York.** — A moving picture apparatus especially designed for the use of salesmen.

**The U. S. Tool Co., Newark, N.J.**—A line of subpresses for various classes of stamped work.

**The Westinghouse Electric and Mfg. Co., Philadelphia, Pa.**—An electric welding outfit which is mounted on a portable truck.

**The Automatic Transportation Co., Buffalo, N.Y.**—A lifting and tiering truck. This truck will pick up and elevate loads to any desired height up to 6 ft.

**The Hamilton Tool Co., Hamilton, Canada.**—A combination chuck and collet. A patented tool that is designed for use in the rapid interchange of drills, reamers, counterbores, etc., on any machine without stopping the machine. The chuck is fitted with Morse taper shank to fit the machine spindle.

**The James Buckley Co., Montreal, Que.**—A new type of tool holder, known as the both way tool holder. This holder is said to be especially for planers or shapers.

**The Climax Company, Montreal, Que.** — A line of belt fasteners, belt lacing machines, and packing. The fasteners are of wire construction and can be laced into the belt either by machine or with a simple hammering tool. The packing is used in extremes of temperatures or pressure such as are sometimes experienced in refrigeration work or rods of pumps of every description. It is claimed that this packing never burns, and does not harden or crystallize.

**Daniel C. Reid, Philadelphia, Pa.** — An ellipsograph. This instrument is claimed to draw all kinds of ellipses and ovals, from 1½ inches up to 12 inches major axis.

**The Joseph T. Ryerson & Son, Chicago, Ill.** — A line of wire nail machines.

**The Sutherland Machine Shops, Omaha.**—A cylinder and boring machine. This small machine will fit on the bed of any lathe, from 14-inch to 24-inch swing, and can be used on either open head or closed cylinder blocks.

**M. H. Derringer, Philadelphia, Pa.**—A special tool holder for lathe use.

**The Link Belt Co., Chicago, Ill.**—A safety mechanical overload release which is especially adaptable for elevating, conveying, and power transmission machinery.

**The D. & M. Guard Co., Rochester, N.Y.**—A safety guard used on any type of punch press.

**The Wahlstrom Tool Co., Brooklyn, N.Y.**—An automatic tapping attachment which is claimed to speed hand tapping. Steel gears provide an oscillating movement, the backward movement clearing the chips. No springs are used, the movement being absolutely mechanical.

**The Berg Burner Co., Brooklyn, N.Y.**—A new design of burner for the burning of oxo-hydrogen gas, automatically produced from oil and water. The burner will operate in any position, and is designed to consume cheap distillates or refined oils.

**The Kent Machine Co., Kent, Ohio.**—A semi-automatic two-spindle pointer. This machine is used for pointing bolts and rods up to three-quarter in. diameter.

**The Cincinnati Ball Crank Co., Cincinnati, Ohio.**—A compression coupling for use on shafts between 15 16ths, and 3 inches.

**J. Merey, Chicago, Ill.**—A marking machine known as a stampograph. This is a rotary machine for lettering and numbering and can be used on any soft metal.

**Guldager and Jantch Co., Detroit, Mich.** A device for the holding of indicators when used on large square with a blade from 2 to 3 inch in width.

**The W. S. Rockwell Co., New York.**—A new line of ship yard angle and plate heating furnaces. Angle heating furnaces are of double end construction, permitting the charging and heating of the material from both ends. Plate heating furnaces have doors of exceptional weight and capacity, and to facilitate opening and closing, are mechanically operated. These furnaces are generally built for oil or gas fuel, although coal may be used if desired.

**The Canadian Hauck Burner Co., Port Hope, Canada.**—A combination lead melting furnace and portable oil burner. When used as a melting furnace 200 lbs of lead or babbit can be melted in 15 min. When not used for melting lead in the pot, the burner may be detached from the furnace, and used for melting babbit out of bearings, re-babbitting, bending pipes, etc.

**The National Acme Co., Cleveland, Ohio.**—A bar pointing machine which meets the requirements of manufacturers in general. Any shaped bars can be handled in this machine and in some cases where quantities of stock are handled, two machines operating end to end are used. A one-horse power motor drives this machine and may be connected to any convenient electrical circuit.

**The Kremer Cummins Machine Co., Cleveland, Ohio.**—A mechanical belt shifter for machine cone pulleys. No part of the shifter is applied directly to the machine or to countershaft. In operating the device, the operator first shifts belt to the next smallest step of cone pulley by operating handles.

**The Dominion Welding Mfg. Co., Montreal.**—An instantaneous water heater combining various features. The burner of this heater is of special type. Those heaters are made for both the trade and domestic use.

**The Gammons-Holman Co., Manchester, Conn.** — A spiral fluted taper reamer that may be used in drilling machines. These reamers are made in all standard sizes.

**The Peerless Machine Co., Rachine, Wis.**—A drill rack that provides for the placing of drills with their points downward, the holes in this stand being drilled cleared through, each having two diameters.

**The H. H. Moore Co., Rochester, N.Y.**—A slotting attachment that can be used on planer or shaper. Will make internal shaping of any description, such as dies, jigs, gauges, keyways, etc. The attachment is made in three sizes.

**The Hunter Saw and Machine Co., Pittsburgh, Pa.**—A special tooth adjustment for inserted tooth saw blades. The arrangement permits the adjustment of one or more teeth independent of the others.

**The Manhattan Machine and Tool Works, Grand Rapids, Mich.** — A four-point screw press that is operated by a special rachet action. The capacity of this press is 80 tons.

**The Wallace Supplies Mfg. Co., Chicago, Ill.**—A machine for the bending of cold bars to any desired shape. The machine will also bend various sizes of pipes.

**The Beard Pneumatic Tool Co., Kansas City.** — A Staybolt cutter that is said to have a strength capable of clipping off staybolts up to 1⅛ diameter at the rate of 1 200 per hour.

**The Eclipse Counter-Bore Co., Ltd., Walkerville, Ont.**—A full line of holders, pilots, core drills, countersinks, counter bores, cutters, and special tools.

**The Roberts Mfg. Co., New Haven, Conn.**—A line of unit jacks and bolt couplers. A surface gauge connection is arranged to work in conjunction with these jacks.

**The Brown Instrument Co., Philadelphia, Pa.**—A new compensated heatmeter. This instrument embodies various new features.

**Edward A. Robinson Co., Montreal.**—An automatic grease cup which when once filled and pressure is applied, the feeding process is constantly maintained until all grease has been delivered to the bearing.

## Selling and Cutting Prices

THE Montreal Daily "Star," in a recent edition, makes use of the words: "It must be remembered, too, that lower prices will stimulate buying." It may be that this referred only to certain lines of merchandise that pass over the counter. It could not refer to selling in general, because the facts are against any such theory having a chance to prove correct.

Start back with the automobile business, the first to put up the price reduction sign. Ford started the business, and in a few weeks car makers, all over the country, irrespective of what their cost sheets told them, were quoting new selling prices. Some orders came in as a result, but it was dealer business, and the ultimate buyer has not come into the market yet as a result of the price reduction. The dealer is loaded up with cars, but the cutting of the price of automobiles did nothing at all toward promoting real, genuine sales to car users. If it had any influence at all, Ford's own big plant would not now be standing idle in Detroit with the workers clamoring for the use of that plant in order that they might make cars for their own use.

Neither could the "Star's" statement be applied with truth to the great field of machine tools, where investments run into very large amounts. When a man goes out to buy machinery he does so because he is going to make something with that machinery. He does not buy because it is cut in price. The "Star" would not put in a new press to-day or a new battery of linotypes because there was a cut rate on. They would put these things in only on one condition, viz., that they had need of them.

The steel market is another case. Prices have been reduced, and yet buying is less. Non-ferrous metals have been riddled as far as their high war marks are concerned and yet to-day they are a drug on the market. Low prices will not sell them.

The "Star's" claim that lower prices stimulate buying should be interpreted in very narrow confines. In some lines of foodstuffs and wearing apparel this may be true, but in the great field of iron, steel, machine tools and equipment in general, it has very little significance.

## Making Income Reports

ACCORDING to reliable information, a number of small shops, some of them in the machinery business, have neglected to make out their reports for the purpose of the income department assessment.

The general excuse is that they do not consider they have a business large enough to make them liable for purposes of the income tax, and therefore they send in no report.

The safest way is to make out the report in full and let the department do the thinking as to whether or not the proprietor is liable to taxation.

Write off a fair amount for depreciation, not more than you are entitled to and not more than you can substantiate in fact if you are called upon to do so.

This paper discussed the matter with the proprietor of a small machine shop, who stated that making out the income tax report was the best piece of business he had ever undertaken: "It gave me an idea of my own affairs that I never secured in any other way. Before I was taking too much for granted, and it was a surprise to learn that some departments that I thought were my best money-makers were not far removed from being cripples. It made me a great deal more keen on collections and on making every department toe the mark. It was a good day for me when I started making out my reports."

This advice is intended, of course, for the smaller plants, for as a rule, the larger concerns have a system that takes care of all these matters.

Remember, the onus for making the returns is placed upon the individual. Do not imagine that you can sit back and wait for the Government authorities to come around and dig you out.

---

In December 30 issue we published three pages of brief items regarding machine tool developments. The two pages to follow are a few more that Canadian Machinery has covered during the past year. The tools included are of the miscellaneous type.

---

Canadian Machinery takes this opportunity of thanking its many friends who forwarded Christmas and New Year's messages during the holiday season. Never before has there been such rare taste in the selection of suitable cards and designs for the sending of holiday greetings. The work, from a technical point, was splendid, and the friends of Machinery are to be congratulated upon patronizing the best print shops in the country, for in no other place could such work be turned out. We thank all heartily who have so remembered our publication.

---

Right at the start of the New Year would be a good time to start some serious study—get headed in one direction. Get on one set of rails and go ahead. The man who does things well will be employed while the tinker is around waiting for something to turn up.

---

The cost of living in Canada was 163 per cent. above 1913 in May of 1920. At December first this had come down 15 per cent. And every decline means that our dollar is getting to look more like a real, respectable, honest-to-goodness dollar should look.

# *Take Advantage of This Situation*

MR. MANUFACTURER: Just a word or so with you.

You are not particularly busy at the plant this month. It may be that part of the works are closed down, and you are not sure when they will reopen.

It may be that you are running part time and trying to make the availbale work spread over as far as possible in the interests of your employees.

However, all that does not make much difference. Here is the point:

Was everything all right in the shop when it was running full blast a few months ago? Were there any operations that you had in mind to make inquiries about?

Were there some pieces where the cost sheets showed that it was taking more time and more money to produce in your plant than in others?

Were there not some old machines on the line that had served their day and generation? They had been written off in depreciation some years ago, and still you hammered away with those old plugs, always saying that just as soon as things let up a bit you intended to replace them with something more in keeping with the rest of your outfit. Yes, that's all true. Well now—

Why not take all these matters up with your machine tool dealer now when he has a chance to talk seriously with you, and to give you the service that he could never do were he busy with orders and shipments. The truth is he has time now to give some real attention to your case.

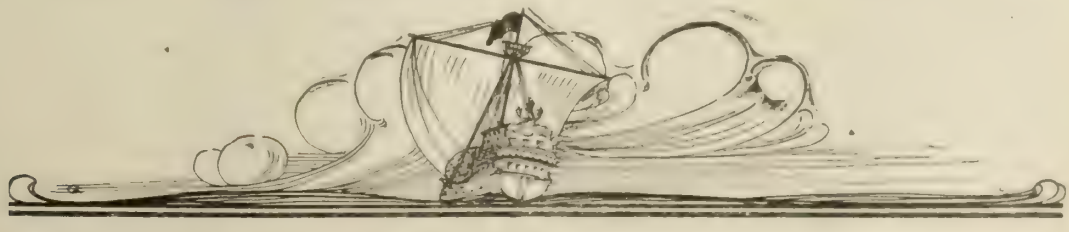
By real attention we do not mean a hurried visit with a grip under his arm and some blue prints, circulars and order forms chucked in his pocket.

We mean this: Ask the engineering department of any good machine tool firm to show you where improvements could be made in your method of production.

Don't let the dealers get away from you too easy. They have often told you that they had machines that would pay you to put in your plant. You were making money then, perhaps, and you were not interested. Most men, when they see the returns coming along all right, are not inclined to worry much about some little old machine that is kind of run down at the heels. It is working, and the results are coming, so there it ends.

But these dealers have told you they could show results that would save money for you?

They have taken blue prints of your work, perhaps, and submitted figures showing just what could be done. But you were busy then and the thing didn't have a chance to get across.



Your plant is not going to be idle long. It is going to start and run again soon, perhaps overtime as well as regular days. You are going to meet stiff competition—harder in many lines than you have ever met in the past.

Your big chance is going to be in having equipment just as good—perhaps a little better—than any other firm in your line of business. Certainly you cannot afford to take a chance in entering into competition with the world with a second-rate equipment. Don't depend on tariffs and adverse exchange rates to keep out foreign-made goods. Get your plant in such shape that your costs will be on a competitive basis with the best of them.

Now remember—machine tool firms have the time to attend to you now, and, what's more, they are in the mood to do it. Get them to show you where they can save money for you with their equipment. If they can put up a good money-saving proposition to you, you are going to be interested. If you are not, then your place is not in the manufacturing business in this day and generation.

Take advantage of the fact that it is a buyers' market. Make use of the service the machine-tool builders have at their disposal for a technical analysis of your manufacturing problems.

Right now is a remarkably good time to take a look over your whole equipment and weed out the weak spots.

# MARKET DEVELOPMENTS

# Believe The Worst Has Happened in Market

## Any Change Now Should be for the Better—Change is Being Made in Pig Iron—Other Prices Stay Much the Same—Buyers Not Coming Into the Markets at Any of the Centres

THE year 1921 starts off quiet in the machine tool, iron and steel markets. Dealers are not expecting a renewal of buying at once, but a number of them will go as far as saying that conditions are not getting any worse, and from this they reason that the peak of the trouble has been reached. Cancellations have been asked for in a number of instances, but the majority of these have not been granted.

One Canadian mill has started one of its bar mills in operation this week. This will roll largely for stock. Buffalo mills are in here making a strong bid for bar iron material just now, and the Canadian mill is called upon to meet this competition. Sheets are selling in fairly large quantities, but the best business just now is being done in tubes.

The Corporation mills continue to roll steel at about 92 per cent. of their capacity, while many of the independents are idle. Pittsburgh reports have many guesses regarding the matter of wages, the one carrying most weight being that wages might be cut right now by some of the independents were they not afraid that a reduction in wages would lead to a demand on the part of the buyers for cheaper steel.

New York reports that machine tool makers are not bulging yet in regard to their selling schedule for 1921. Makers probably realize that in the present temper of the market a reduction in price would not bring in any new business. Dealers in this district agree that this is the case, holding that when machine tools are wanted, they are bought almost regardless of any reduction in price.

The scrap metal trade continues in the slump. It has been there for many weeks now and little trade is being done. The larger yards persist in their attitude not to buy anything except enough to cover their contracts.

# QUIET OF HOLIDAY SEASON IS STILL IN MONTREAL MARKET

Special to CANADIAN MACHINERY.

MONTREAL, Que., Jan. 6.—Industrial adjustment in the nature of wages and working conditions, promises to be a feature throughout the coming weeks. It is not that industry has had a bad year financially, but rather that high wages must be diluted in some degree to conform to the new analysis required to maintain well balanced trading throughout the coming and succeeding years. In establishing this new industrial formula it is essential that the component ingredients be carefully selected and arranged before doses in large volume can be administered, but when in a condition for regular and advanced treatment, the convalescent period of invalid industry will be ushered in to the tune of greater activity in every line of manufacture.

### Looking for Summer Activity

The coming of the new year has not opened up any new channels of interest in steel circles, apart from the fact that dealers are far from being cast down by the existing quiet character of general business. The great bulk of steel demand, just now, is for urgent need only. so that consumers are not overstocked with supplies of any kind. Most of the mills are operating light so that surplus stocks are not over-abundant. This condition promises well for an early return to normal activity when the trade and the public generally feel that the hour has arrived for geting back into working harness. "The past year has been filled with many interesting features, and while the latter months have caused us some anxiety, we have never been discouraged, realizing that some such depression must come sooner or later before trading could be returned to a sound working basis, a condition that has not existed since the middle of 1914." "The intervening years," continued the dealer," have passed by with conditions more or less of an artificial nature, intermixed with excessive demand and abnormal price fluctuations, but never with the assurance of permanency, either in the way of production or in the cost of materials. It is necessary, therefore that the irregularities of industry, liquidation or mutual adjustment of high priced goods, better regulation of wage scales and working conditions, should be arranged to suit the changing circumstances. We are now carrying sufficient supplies in warehouse to meet all requirements of the trade, but are not overloading ourselves, for the reason that the present lull is prevalent throughout the country, and that all activity is more or less in repose." It would appear that dealers are not expecting any heavy buying before March at the earliest, but many are anticipating a fairly active period before the summer months are far advanced. All price quotations are of a nominal character and unchanged. Further revision downward is not unlikely.

### Tool Trade Very Quiet

The machinery trade seems to be facing a period of comparatively light buying, as a result of the unsettled state of trade, and the tendency on the part of many manufacturers to curtail operations while industry is adjusting itself to its changing surroundings. Purchasing agents, in many cases, are instructed to buy conservatively during this period of transition, and in consequence it is often difficult to secure their business interest, let alone an order for equipment. Many, however, intimate that their normal needs are under-supplied, and a renewal of general activity would mean additional or renewed equipment.

More than ordinary attention has been given recently to the clearing out of existing stock, which, in many instances, was acquired at higher figures than could be obtained for similar tools at the present time. Some dealers are fortunate in having small stocks on hand, while others are carrying considerable equipment purchased during the past year or two, much of which, however, was secured in bulk, so that a lot of it could be sacrificed and still leave the dealer with a small profit. The holiday weeks provided a quiet period for many dealers and the volume of business was comparatively low for most houses, some of which had their men off the road for the entire week.

**Active Period May Follow Lull**

"We may as well be out of business for all we are doing just now. However, we must take the rough with the smooth, and as the past several years have enabled us to weather a short period of depression, we are content to carry on at a slight loss, in the expectation that the year will not be far advanced before things begin to right themselves. For the present prices may as well remain where they are, although a revision would result in lower quotations." This statement from a dealer here indicates the extent of trade in old materials, but the passiveness is counteracted by the belief that business will show a gradual picking up after a few more weeks of slow trading.

## POINTS IN WEEK'S MARKETING NOTES

**There is no change in the scrap metal situation, yards still reporting little being done in any line. Many of them are still out of the market for any non-ferrous lines.**

—

**A new price on pig iron is being brought out, which will show a reduction.**

—

**Buffalo firms are making a bid for the bar iron trade in this district. Another bar iron mill was put in operation by the Steel Co. of Canada this week.**

—

**Tubes continue in good demand, but the price remains unchanged.**

—

**The Steel Corporation mills continue to operate at 92 per cent. of capacity, while most of the independents are down.**

—

**Machine tool dealers in the district have no intimation of new prices by the makers.**

—

**Pittsburg claims that some of the steel mills would cut wages, but fear such a move would lead to a demand on the part of consumers for cheaper steel.**

## QUIET WEEK IN TORONTO TRADE

**No Intimation Given of Intention to Make Reductions in the Selling Schedules**

TORONTO.—Although it is generally anticipated that trade will improve soon, it is hardly to be expected that a change would be felt in the first few business days of the year. Trade is quiet in nearly all lines, and buying for the most part is confined to actual wants. If a firm can do without a machine tool or an order of steel, it is being done without, and it might also be added that in some cases if they can do without paying promptly for anything or everything they secure they are following the same policy.

Dealers say they have no intimation of any change in selling schedules on which to work this year. It might have been expected that new prices would have come out around the first of the year. It is reported that some of the makers have still on hand fairly large stocks of raw materials, and they feel that until they have worked these out they should not make any material reduction in prices. It is also doubtful whether there would be any advantage from a reduction in price at this time. As a general thing, when a man buys a machine tool he does so because he has some definite purpose in view—he is going to make something, and the matter of a few hundred in price would neither drive him from the market nor bring him into it.

There are some inquiries in the market now. They are, for the most part, rather small, and consist of replacements or minor additions to existing plants.

Small tools are selling also on the hand-to-mouth policy, and the whole territory is being worked for all available business. There are few firms carrying any very large supplies of small tools, and the low rate of operations in many cases justifies this position, and offers no good reason why a firm should change its attitude.

**The Steel Market**

Bar Iron.—There is a fairly heavy stock of bar iron in the warehouses of this district. Buying is not very brisk yet, but mills are working putting in stock for the buying they expect to come later on. Steel Co. of Canada started a bar mill running this week, which has been down for some time past. The mills at Buffalo are making a strong bid to get into this district, and they are offering prices at times that make it very plain they are out to secure business. The Canadian firms, therefore, are under the necessity of meeting this competition. Bars are quoted for prompt delivery from stocks at 4.75c per pound.

Sheets.—The demand for sheets has continued fairly strong this season, and the weather has helped in this to some extent. The open season has the effect of allowing outside work to go ahead. Stocks held at present are fair, but were a buying movement of any size to start, the merchants would soon have to come into the market in order to secure supplies. The one sheet mill in this district is fairly well supplied with orders, which should keep it in operation for a couple of months yet.

Plate.—Demand very light at present, and has been for some weeks owing largely to falling off in shipbuilding in this district. Warehouses are quoting 5.50 to 6c, and delivery can be made on short order.

Tubes.—There is a good trade being done in tubes. The price is still holding the same, and remains well above the pre-war list. It is about the last item to show real strength, and so far is the hold-out of the market in the matter of reduction.

## AS A WHOLE 1920 WAS A GOOD YEAR FOR U.S. MACHINE TOOL TRADE

Special to CANADIAN MACHINERY.

NEW YORK, Jan. 6, 1921.—The year just closed has been a very profitable one for the machine-tool industry of the United States notwithstanding the unsettled conditions of the past few months. In the first half of the year business was exceptionally good. The period of activity in buying started about the middle of 1919 and continued almost without interruption until May or June, 1920. In April the railroad strike occurred and later there was the coal strike, both of which created a shortage of steel and coal and made it impossible for some plants to work at full capacity. Coincident with these factors was the tightness of money. As a result, the period of cancellations began about the middle of 1920, though there was also a good share of new business at the same time. Some manufacturers and dealers had a satisfactory trade almost to the end of September, taking into account both orders and shipments.

At the beginning of 1921 some machine-tool manufacturers find themselves in a rather unsatisfactory position. Many of them have been left with large stocks of high-priced pig iron, steel, castings and other machine-tool parts. If they were to take too large a loss on this inventory it would seriously [illegible]

financial condition, despite the large profits which they have made in the last few years. One plant is said to have $1,000,000 in capital tied up in such raw or partly finished material. It becomes a serious problem just how to meet the evident expectations of buyers of lower prices on tools. With few exceptions, machine-tool manufacturers have not made reductions, but fear that they will be obliged to do so within the next 30 or 60 days. One engine lathe manufacturer announced a 12½ per cent. cut, effective January 1, but, generally, the builders are still holding out for the same prices as have prevailed throughout the greater part of 1920. An occasional concession is heard of, particularly when dealers are competing for business. Such concessions usually come out of the dealer's commissions.

Some business is expected to develop during the first two or three months of the new year, but it is not likely that there will be any rapid recovery in buying. In some quarters it is thought that most all of 1921 will be quiet as compared with the business that was done in 1919 and 1920. There is a considerable amount of dormant business—that is, the inquiries have been sent out in recent weeks, but buying has been postponed. Whether a goodly share of this prospective buying will materialize remains to be seen.

# MAY HAVE TO MAKE MORE PRICE CHANGES TO CONVINCE BUYERS

Special to CANADIAN MACHINERY.

PITTSBURGH, January 6.—Mills that closed in the latter part of December are not resuming this week to any great extent. Resumption hinges upon the accumulation of orders, whether strictly new business, specifications against old contracts or releases from suspensions, and the accumulation has been very slow. A change in conditions is requisite to enable the independents to operate at any considerable rate, and while such change has been predicted in most quarters as likely to occur after January 1, the change can hardly be expected in the first few days of the new year.

As to the United States Steel Corporation, it continues to operate up to the physical limit, and with a few additional blast furnaces blown in during the past two months, on account of supplies of coal and coke being improved, the corporation's operations are somewhat heavier than for many months, at about 92 per cent. of capacity, measured in steel making units in operation.

With the corporation operating at 92 per cent., there is an ingot production at the rate of fully 21,000,000 tons a year, and at an estimate of 20 per cent. for the independents, counting, of course, those that are closed entirely, there is 6,000,000 tons more, making 27,000,000 tons altogether, there is production at about 65 per cent. of the 42,000,000 ton average rate obtaining during the first nine months of 1920, when the demand for steel was regarded as remarkably heavy. Considering the stagnation prevailing almost everywhere, one would suppose that consumption of steel had decreased by more than one-third. If so, the prospect for the immediate future is not heavier production, but lighter production. It would be necessary to account for the present production, and it seems quite possible that some of the steel being shipped by the Steel Corporation is going to replenish stocks.

### Prospects for Consumption

Obviously it is a question of when the ultimate consumer will take hold. It is not a question directly of when the fabricating shops, car shops, machinery manufacturers, bolt, rivet and nut makers, spike manufacturers, agricultural implement makers, producers of cold finished steel bars, and the various other "manufacturing consumers" will decide to buy steel from the mills, but a question when the customers of these steel consumers will themselves be disposed to buy. The manufacturing consumers will buy only as they see a market for their various finished products.

The readjustment the country is now undergoing is of course chiefly a readjustment in prices for materials and services. Consequently it is not enough for mill prices of rolled steel products to be readjusted. There must be readjustment in prices all along the line down to the ultimate consumer. Assuming for the sake of argument that mill prices have been readjusted adequately, it is a fact that prices of manufactured goods have not in all cases been readjusted in keeping. The manufacturing consumer cannot stand between the steel mill and the public and put in his own pocket the reduction the steel mill makes. To illustrate, at the top of the last price movement before the war, culminating late in 1912, steel bars reached 1.40c, while standard railroad spikes reached 1.85c. Merchant bars, as now equalized between the Steel Corporation and independents, are 2.35c, which is 67 per cent. advance. Assuming for argument that this extra price is justifiable, there is the condition that when, recently, spikes declined to 3.65c, they were regarded as readjusted, but they are 97 per cent. above the 1.85c price. If the spike makers cannot "afford" to sell at less than 3.65c, then there is something wrong with their costs and the country will wait until they have readjusted those costs.

### Pipe Gets in Line

The year 1920 in the finished steel market ended nicely by the independent market on steel pipe coming down on the last day, for under date of December 31, 1920, the Republic Iron & Steel Company issued a new card showing the same discounts as in the Industrial Board schedule of March 21, 1919, the card to which the United States Steel Corporation has uniformly adhered all this time. The other independents will necessarily have to do likewise and it is an unimportant detail what dates their revised cards may carry. The reduction is from a basing discount, on ¾ to 3-inch, of 54 per cent. to a basing discount of 57½ per cent., making $7 a net ton change.

Pipe was the remaining item in the regular steel mill products to be adjusted. The independent price on tin plate came down to the Steel Corporation price of $7 per base box, 100-pound, about the middle of November. On November 26 bars, shapes and plates came down to the Steel Corporation or Industrial Board prices of 2.35c, 2.45c, and 2.65c, respectively. November 29 wire and nails came down to 3.25c for wire and $3.25 for nails, and a few days later sheets came down to 3.55c for blue annealed, 4.35c for black and 5.70c for galvanized.

Thus the whole round trip of independent steel prices was made just within the limits of the calendar year 1920. It is true that late in 1919 the independents in certain lines were quite generally securing prices above the Steel Corporation or Industrial Board prices, but those prices could be regarded simply as containing delivery premiums, the mills not being willing to sell and the buyers not being willing to buy for any distance ahead. It was after Chairman Gary of the Steel Corporation made his statement, December 30, 1919, that the corporation would not advance its prices, that the independents saw that they would really have to "go it alone" and then they regarded their advance prices as regular prices, not as premium or temporary prices.

### Prospective Steel Prices

In view of the fact that there is not likely to be any general buying movement in steel products in the near future, say not earlier than three months hence, steel manufacturers would prefer it to be assumed that present prices represent the prospective bottom, but the fact may as well be stated plainly that this is not the more likely prospect. The balance of probabilities is that the low point in steel prices, on which the market will eventually turn and from which it will stiffen, will be lower than the present level, say from 2.00c to 2.20c for bars, shapes and plates. If such prices come, they will not be developed soon. There is no incentive for a mill to name such close prices unless, or until, it sees an opportunity to fill up fairly well and thus obtain an economical operation.

As to wages, reductions by independents' mills have not been proceeding nearly as fast as seemed likely two or

three weeks ago. The majority of independents are holding off, awaiting a further reduction in the cost of living and also being desirous that the present plant idleness may have its full moral effect both upon workmen and the retail stores they patronize. Some mills, too, attach much importance to the theory that immediately upon wage reductions being made steel buyers would expect lower prices for steel.

At the opening of business this week a large valley pig iron producer announced its willingness to sell basic iron at $30 and Bessemer iron at $32, valley, thus recording declines of $3 in each grade from the previous nominal quotations. Foundry iron, formerly quotable at $35, valley, is not plainly marked at any price, but will have to readjust itself to no more than a moderate spread above basic.

# EDMONTON STANDS AT GATE OF NEW COUNTRY AWAY TO NORTH

A. M. FRITH, secretary of the Edmonton Board of Trade, writing to this paper of conditions in that centre during 1920, says:—

Commercial development in Edmonton during 1920 has been very pronounced. In addition to a considerable number of new firms, which have been established in the city, both manufacturing and distributing, many important additions have been made to plants and warehouses already established.

One of these is the erection of a nine storey warehouse for Marshall Wells, Alberta, Ltd., this building being the largest warehouse devoted to one line in western Canada, outside of Winnipeg. It is expected that the building will be ready for occupancy about December 1st. It will be one of the most complete and best equipped buildings of its kind in the country.

Work has also been started on an addition to the already large warehouse of Revillon Wholesale, Ltd. The plans for this building will make it, when completed, the largest commercial warehouse in the Dominion, with 11 acres of floor space, a frontage of 350 feet by 150 feet in depth, nine storeys high. Another important development is the erection of a new factory for the North West Biscuit Company at a cost of $500,000. This company is already the second largest exclusive biscuit factory in Canada and the new building will have double the capacity of that at present occupied.

Perhaps the most important development in the commercial life of Edmonton during the year has been the acquisition by lease of the Edmonton, Dunvegan and British Columbia Railway by the C.P.R. The inevitable result of this will be a very greatly improved service to the Peace River and Grande Prairie countries, followed by a great influx of settlers and business men to that fertile region of which Edmonton is the natural distributing centre. A great number of new settlers have gone into the Peace River country this year, and from present prospects this number will be very materially increased in 1921. Enquiries regarding Peace River are coming from all parts of the United States and the Old Country and no less than 2,000 soldier settlers have been located on farms in that district during the last few months. It is a fact that by far the greatest number of soldier settlers have taken up land in Alberta, this Province leading by a big margin all the other Provinces in Canada. Over $13,000,000 has been authorized by the local office of the Soldiers' Settlement Board for advances to soldiers, for the purchase of land, livestock or farm machinery.

Another important factor in the commercial development of Edmonton is the extensive work being conducted by many strong companies in the oil fields of Northern Alberta. Chief among these is the Imperial Oil Company, the Union Oil Company and some syndicates financed by British capital. The operations of the former have resulted in the discovery of oil at Fort Norman on the Mackenzie River. Oil was discovered at a depth of about 600 feet and further drilling will be done in that vicinity next spring, those in charge of the work being convinced that oil will, within a short time, be found in large quantities. In view of the urgent need of petroleum and its vital place in industry at the present time, the particular significance of this discovery and the operations leading to the development of further oil deposits will be apparent.

Edmonton, however, will depend in the future, as it has in the past, very largely upon the development of the rich agricultural land in Central and Northern Alberta. Greater attention is being given all the time to the possibilities for wealth in mixed farming in this district. This is seen in the steadily increasing value of farm lands and the growing demand, particularly on the part of Americans from the bordering States, for improved farms in this territory. During the year a large number of American farmers, most of them with an ample supply of capital, have purchased improved farms and from the enquiries which are being received it is evident that this number will be very greatly increased.

With the timber resources of this Province practically untouched, with one-seventh of the total known coal deposits of the world within its borders and the consequent possibility of an unlimited suppy of cheap power, it seems inevitable that an extensive industrial community will be established by which the markets of the western Provinces will be supplied from this city or district.

In view of all these developments, therefore, it must be stated that the future prospects for Edmonton have never been better than they are at the present time, and business men with one accord are extremely optimistic in respect to prospects for greatly increased business during 1921.

# CANADA NINE DAYS AWAY FROM JAPAN

**Believes Trade Could Be Developed That Would Be to the Interest of Dominion**

A summary of an article in a recent edition of the Trade Bulletin from Ottawa, gives the following:

Canada's place in the future development of Japan should be studied. Many things are in our favor. We are the nearest of all western nations to Japan. Vancouver is to-day nine days from Yokohama and San Francisco is 20. This is due largely to the excellence of Canadian ocean service. Canada must put herself more firmly on the business map. A better cable service and a national news service is necessary.

Japan is developing very rapidly and her needs are many. In Japan it is the age of building. Many of the roads of Japan are execrable, but the growth of interprovincial transportation has brought forward the subject of state developed trunk roads, and it is even now under consideration. Herein lie openings for Canadian road-making machinery, and timbers, and later for the increased importation of bicycles, automobiles and accessories. In the renewing of the Japanese cities, there is market for Canadian steel and iron, for nails and bolts, iron pipes and wire, and all wood and iron working machinery. Agricultural implements will be in demand, for the wages in the cities will inevitably drain the cheap labor from the rural districts.

**Hopeful for 1921.**—The annual travelers' convention of the Ontario Wind Engine & Pump Company, Toronto, manufacturers of Toronto farm equipment, was held at the head office of the company. Every traveller felt optimistic concerning business in 1921. Many thought that the volume of sales would exceed 1920, which in itself was a record year. In support of their contention they stated that farmers were swinging over from the buying of luxuries to the buying of necessities, and it was predicted that spring would bring some healthy buying; also the farmers were figuring on planting a large acreage in 1921.

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

## ENGINEERING

The High School Board, Burlington, Ont., is planning the erection of a school costing $75,000.

The Electro-Foundries, whose building was destroyed by fire recently, will be rebuilt at once.

Phillips Steel & Wire Co., St. Patrick street, Montreal, are erecting a warehouse costing $7,500.

The Royal Bank of Canada are erecting a bank in the spring at Dodsland, Sask., at a cost of $10,000.

The erection of an oil-distributing warehouse is being planned by the McColl Bros., Regina, Sask.

Tenders will be called in a short time for the erection of a high school to cost $200,000 for Board of Education, London, Ont.

The Cecil Investment Co. are contemplating at an early date the erection of a $1,000,000 hotel at 22 Sparks street, Ottawa, Ont.

Plans are being prepared for a tourist hotel costing $300,000 at Kelowna, B. C. Tenders will probably be called in the spring.

A factory building will be erected on Dawes Road, Toronto, at a cost of $38,000, by Andrew Buchanan and Sons, Glasgow, Scotland.

The Farmers' Co-operative Packing Co., St. Boniface, Man., plans to erect a cold storage addition to their plant there. The estimated cost is $200,000.

A by-law will be submitted to the ratepayers early in January, authorizing construction of a memorial hospital to cost $37,000 for Perth Memorial Hospital Board.

The American firm of Steel Sash, Ltd., have established a Canadian branch at London, Ont. Machinery is being installed and manufacture will commence early next month.

The Prov. Govt. Dept. Pub. Works, Toronto, are planning the erection of a new administration and office building, costing $1,500,000. Estimates will probably be presented at next sitting of Legislature.

Application will be made to the Parliament of Canada at the next session for an act to incorporate a company under the name of the Mackenzie River Petroleum Co., Ltd., with the powers incident to the production of oil and natural gas and the marketing and transportation, except by rail.

## SEVERAL CHANGES MADE IN THE SELLING FORCE OF JOHN MORROW CO.

THE management of John Morrow Screw & Nut Co., Limited, Ingersoll, Canada, has taken advantage of the holiday season to reorganize the company's selling force.

The company has established at 489 St. Paul street west, Montreal, an office and warehouse. This branch will be in charge of F. J. McCarty. Mr. McCarty is an experienced tool maker, and has had, in addition, a large business experience, having been intimately and favorably known to the trade of the Montreal territory for several years past. The services of Mr. McCarty and his staff will be exclusively devoted to the interests of the customers of John Morrow Screw & Nut Company, Limited, and the Ingersoll File Company, Limited, for which the Morrow Company are the sole distributors.

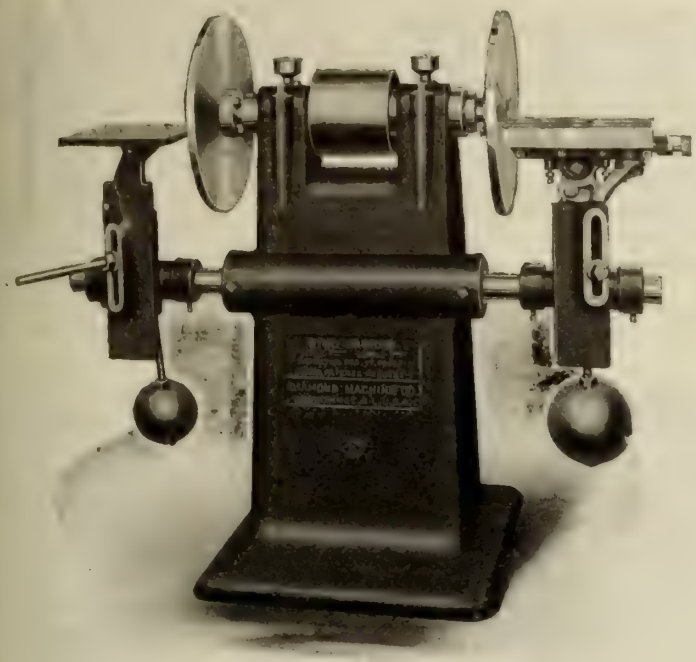
In Central Ontario a change has also been made. J. C. Adams, Toronto, now represents the Morrow Company in this territory. He, too, has the advantage of having had actual shop training. After leaving the bench he was for several years connected with the Vokes Hardware Co., Toronto, and since being demobilized from the Royal Air Force has been in the service of one of Canada's largest manufacturing concerns. He will devote his time exclusively to the work of the John Morrow Screw & Nut Company, Limited, and Ingersoll File Company, Limited.

J. C. ADAMS

H. P. Stoneman, assistant general manager, is at present in western Canada completing arrangements whereby the Morrow Company will be adequately represented on the Prairies and the Pacific Coast.

In an interview with a representative of this publication the other day, J. F. MacKay, who assumed the duties of vice-president and general manager of the company on November 1st last, stated that the Morrow Company has been running at capacity practically throughout the entire year, sales showing substantial increases over the corresponding months of the previous year.

Mr. MacKay further stated that from orders already on the company's books, and from inquiries being received daily, he was of the opinion it would be a matter of but a few weeks when the full equipment and force of the company would again be required to keep up with the demand.



In an interesting letter addressed by the company to each employee at the close of the year, the announcement is made that by means of a bonus system inaugurated one year ago the wages of every employee—excepting the executive officers—has been increased by 22½ per cent. during the year, and that the total amount so distributed was over $77,000. The same system will be continued for some time to come.

---

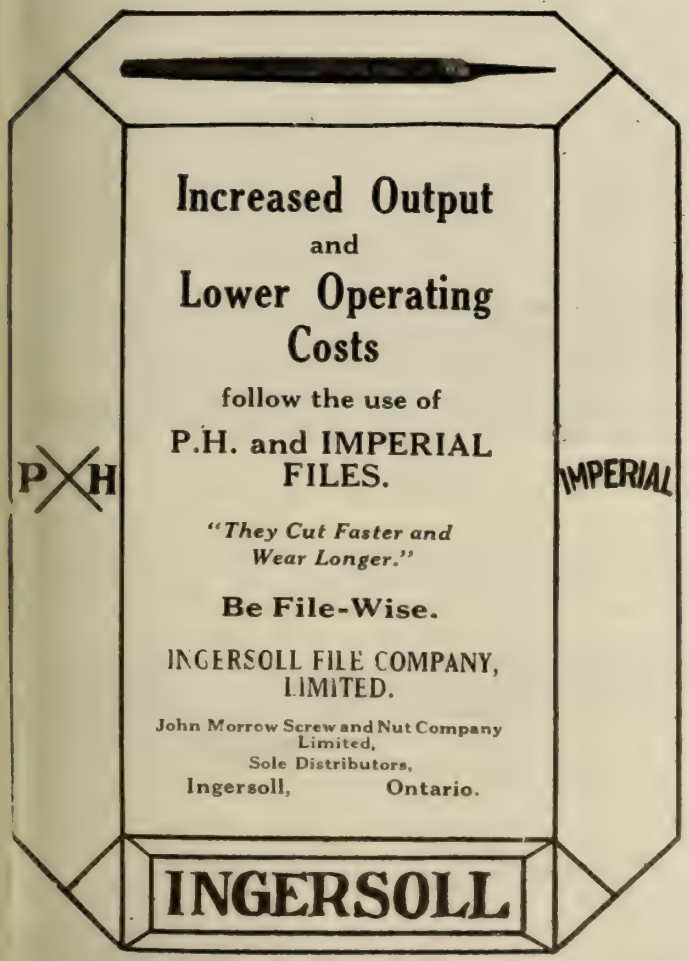
A large uptown restaurant is being planned in the vicinity of Avenue Road and Bloor St., Toronto, by Col. McLean, proprietor of the Venetian Gardens in Montreal.

Plans for the construction of a power plant on Green River next spring for the development of from 2,000 to 2,500 h.p. are being made by the Madawaska Light and Power Co., St. John, N.B.

The Billings and Spencer foundry at Welland has been closed for a readjustment of business. The notices which were posted up stated that all employees were free to seek employment elsewhere.

# DIAMOND
## DISC GRINDERS

Good grinding in fast time has made the Diamond popular in a host of shops. The right design and build eliminate vibration and give the operator a perfect surface every time. There is a suitable size and equipment for every surface grinding job you have. Workmanship and material of "Diamond" quality throughout.



May we send you catalogue?

# FINDS GERMAN GOODS NOW SELLING IN BRITISH MARKET

MR GEORGE A. MARSHALL, of Marshall Son & Bunney, and also connected with the Canadian Association of British Manufacturers, has returned from an extended trip to England, making a survey of the steel and cutlery districts. Mr. Marshall found a good many instances where German-made goods were being sold in London in direct competition with British made.

"It is surprising the way in which German goods are coming back into the markets," said Mr. Marshall, in discussing the matter with Canadian Machinery. "Dealers tell me that when it comes to a sale and the difference of price is in favor of the German article, the sale will follow the price. Germany, according to all reports I could gather, is recovering very rapidly, and it is largely due to the efforts of the working people, whereas in England the labor market is still indifferent, to say the least. The attitude of the workers is greatly changed from the time when I was last over in 1914, and it seems impossible to get anything like the production returns of the former days, while the rate of wages is still very high. There is of course considerable unemployment, but even that does not seem to have made much difference in the rate of wages."

Living is still high in England, no matter what lines are purchased. Merchants in many cases are making much higher profits than they ever did in days before the war, and thy are fighting to retain the margin of profit.

"The war effort of the Old Country was too great for the people there to stand in many cases," is Mr. Marshall's belief. He recalled several families that had been shattered by the inroads of the war, and the remaining members, fathers and mothers in several instances, were nervous and physical wrecks, the strain having been more than they were able to bear.

Some lines of industry have found it difficult to get under way because there were such enormous stocks piled up from the days of the war, especially in lines of tool steel.

Mr. Marshall called on a number of firms whose goods he handles in Canada, and was also a visitor at the headquarters of the Association of British Manufacturers and their agents, finding that body in a very prosperous state, and developing a large amount of world-wide trade.

"But Toronto looks good to me," concluded Mr. Marshall. This paper was the least bit surprised to hear such an admission from such a staunch Britisher, and such a lover of England. "I was really very glad to get back to Canada, and I tell you Toronto is a lovely city and a fine place to live."

### Firms Want to Establish Trade Relations With Canada

Information regarding the following lines can be obtained by communicating with this paper and mentioning key numbers:

2594, Bright Nuts and Bolts.—A Manchester firm inquires for manufacturers of bright nuts and bolts who are in a position to export. Samples and prices are requested.

2595, Colliery Rails and Tubs.—A Manchester firm are open to consider offers of colliery rails and tubs.

2596, Castings.—A Manchester firm are in the market for malleable iron and steel castings.

2597.—Gasolene Farm Engines.—A Japanese firm of agricultural implement importers in the Hokkaide are anxious to hear from Canadian manufacturers of gasolene engines. The firm is at pres ent importing from the United State but would be glad to give preferenc to Canadian manufacturers. The siz most is demand is 1¾ horsepower mod with magneto ignition, adaptable eithe to gasolene or kerosene, but all sizes u to 8 or 10 horsepower are importe Catalogues and c. i. f. prices are re quested immediately.

2600, Asbestos.—A Nottingham fir are open to consider offers of fibre an sheet asbestos, washers and packings.

2601, Graphite.—A Nottingham fir would like to receive prices and sample of any Canadian graphite that may b on offer.

---

A memorial arch is being contemplate by the pupils and graduates of the Roy al Military College, Kingston, Ont., t the memory of the many cadets and ex cadets that fell during the war. Est mated cost, $60,000.

# FIRST QUARTER BUSINESS IN 1921 WILL BE ABOUT AT PRESENT LEVELS

THE prediction which we ventured to make a year ago has been largely verified by the course of the market itself. Owing to the disorganized condition of the American railroads, even after their return to the management of their respective companies, deliveries of material were for a long time uncertain. This has now been practically overcome and conditions more or less normal can now be said to prevail.

The coal situation, which was almost in the nature of a famine, resulted in high prices prevailing for iron and steel products during the greater part of the year. While it was evident that prices would eventually come down, it was not until the month of October that the prevailing wave of deflation made its influence felt in iron and steel. Since then premium prices have almost disappeared, and the year closes with quotations on the majority of iron and steel commodities at the level of prices instituted by the Industrial Board of the United States in 1919. The United States Steel Corporation is now rapidly overtaking its old contracts, and is starting to ship freely to this market.

There has been a marked absence of buying both in the States and Canada during the past month and as a result some of the mills in the States are only in partial operation, while others are closing down until sufficient orders accumulate to warrant their starting up again. In the meantime buyers are refraining from placing contracts and are purchasing only what their absolute needs demand.

Under prevailing circumstances it is very improbable that there will be any advance in present price levels during the first quarter of 1921. On the other hand, when the time arrives that the United States Steel Corporation is in a position to handle prompt shipment business, it may be decided that a reduction in wage costs is necessary, with the view of reducing prices in an orderly fashion and so preventing any individual price cutting. Reduction in wages must necessarily be gradual, as the cost of living goes down, and it will, therefore, be a long time before the pre-war standard of prices on iron and steel commodities will be reached. Our view is that for the first quarter of 1921 prices will remain at about their present level.

Business generally in Canada has been good throughout the year. There is no reason to doubt that this will be reflected in the balance sheets of all the large producing companies. Most of them have wisely laid up sufficient reserves to tide them over a period of deflation and they are thus in a position to meet the present quietness without anxiety. There has been no speculation and no undue inflation and consequently nothing in the nature of a collapse is possible.

J. T. McCALL,
President and General Manager,
Drummond, McCall & Company, Limited.

Dec. 30, 1920.

# NUMBER OF NEW FIRMS GOT A START IN BRANTFORD IN 1920

REVIEWING the progress made in Brantford during the year 1920, W. H. Wood, managing secretary of the Chamber of Commerce states:—

During the year 1920 the following large concerns commenced production in the Brantford plants:—

Robbins and Myers, of Springfield, Ohio., manufacturers of fractional horsepower motors, fans and other small electrical appliances.

J. & J. Cash, Inc., with plants in Norwalk, Conn., and Coventry, England, manufacturers of woven names.

S. C. Johnson & Sons of Racine, Wis., manufacturers of floorwax, stains, wood finishes and freeze-proof, carbon remover, cleaner, polish, etc., for automobiles.

The Wm. Sparling Co., of Toronto, Ontario, and the H. K. Ferguson Co., of Cleveland, Ohio., construction engineers, opened offices in the telephone city to care for their contracts in this part of the province.

The McClary Stove Company, of London, Ont., purchased the Wm. Buck Stove Company, and have greatly increased production in their Brantford plant.

The Williams Tool Corporation of Canada, Limited, manufacturers of pipe threading machinery, amalgamated with the J. H. Hall & Sons plant. The Williams people are from Erie, Pa., and are caring for their Canadian trade as well as that formerly held by the Hall Co., from their Brantford plant.

The Brantford Emery Wheel Co., Ltd., is now the Canadian plant of the Waltham Grinding Wheel Co., of Waltham, Mass.

The Brantford Computing Scale Co., Ltd., are now a million dollar concern, and are completing their excellent new factory, which will soon be occupied and make it possible for them to meet the demands of their business as well as to care for their new lines.

The Dominion Flour Mills, Limited, are now occupying an excellent new red pressed brick mill which was erected in the fall of 1920.

The Cockshutt Plow Co. again increased their immense plant by the addition of a large smithy.

The A. C. Spark Plug plant is completed, which, with over sixteen acres of land, has been purchased outright by the General Motors Corporation.

The Brantford Brass Foundry Company has commenced production.

The Brantford Machine & Tool Co. has been taken over by a new textile company.

Ham Brothers, manufacturers of refrigerators, bee keeper's supplies, screen doors, kitchen cabinets, have made another large addition to their plant.

The Blue Bird Co., manufacturers of electric washing machines, and household electrical appliances, are also securing production.

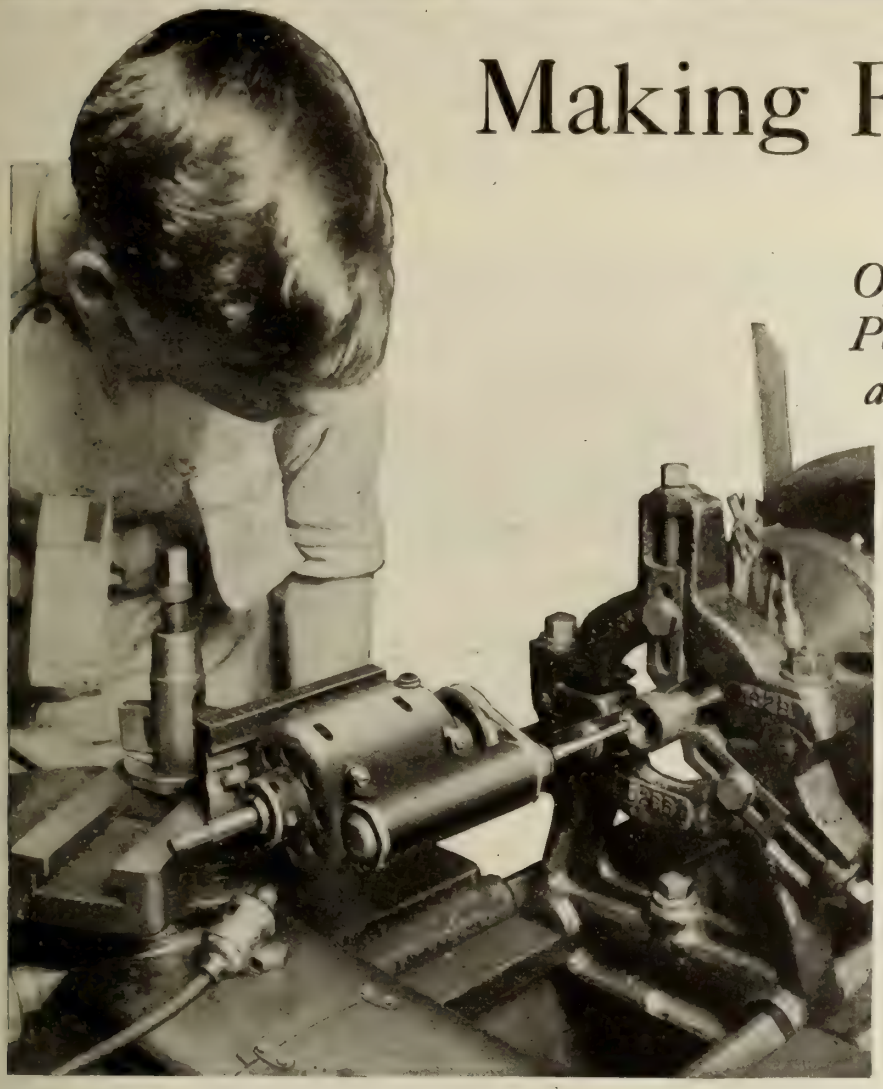
The Ontario Portland Cement Co., headquarters at Brantford, are now constructing their plant at Beachville, Ontario.

Several other industries from the United States are looking quite favorably upon the telephone city as being the centre which meets the requirements considered when seeking a location. There are now a score of United States concerns who have their Canadian plants in Brantford.

## PERSONAL

George Wedlake, general manager of the Cockshutt Plow Co., Brantford, was elected mayor in the civic elections this week, having a majority and a plurality as well. The result was a remarkable tribute to the esteem in which Mr. Wedlake is held in the community. He has been on the Hydro Commission of that city for some years. Mr. Wedlake has been with the Cockshutt Plow Co. for many years, starting there as a molder, and working his way on up to the position of general manager. Mr. Wedlake has a plain and direct method of talking to men, and when he gives his word on a point it is accepted as as good as finished already. Mayor-elect Wedlake should be able to serve his city well.

A permit has been granted to the Imperial Oil, Ltd., for the erection of a steel warehouse, storage tanks and stables on the corner of Market and Water Sts., Gananoque, Ont.



**Tenders Called.**— Tenders are called up to January 11, for building a bridge over the Burlington Channel, Ont. The structure is to be single leaf Strauss trunnion bascule. Address R. C. Desrochers, Ottawa, from whom blue prints can be secured.

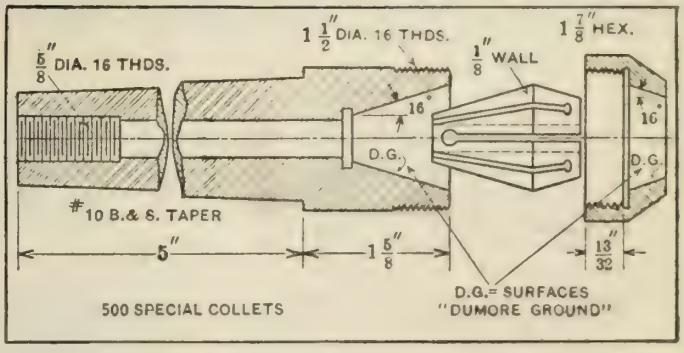
A company has been formed under the name of the British Columbia Steel Works, Ltd., by the amalgamation of the Port Moody, Eburne and Tudhope Electrical plants. Each of these plants will continue to operate on its present location, pending concentration of all of them at Port Moody.

—Darling, in Des Moines "Register."

**Surely There Must be a Better Way to Gather Apples**

# Making Fine Tools

## *An Interesting Operation, Economically Performed by Means of a DUMORE Grinder*



This photograph — taken at the City Engineering Company's (Dayton, Ohio) plant shows a Dumore Grinder finishing the main shank and head of a special draw-in collet. There were 500 put through in this special lot and the time for the operation shown averaged 8 minutes per piece.

The second operation; grinding the internal face of the collet nut, was also performed by this convenient precision tool.

Dumore Grinders are popular here as in every plant where fine tools are made. Their accuracy makes them useful for the finest finishing work; their simplicity and convenience make them practical for many difficult, almost inaccessible jobs.

Dumore Grinders transform any lathe into a precision grinder; they make fine finishing possible in every machine shop.

***May we tell you more about them?***

## TRADE GOSSIP

BIG EXPENDITURE.—The Toronto Harbor Commission, at its weekly meeting had the estimates for the next year under consideration. It is proposed to spend upwards of $4,000,000 on the completion of the Sunnyside-Humber development, including the top dressings of the boulevard and bridle paths, further extension of the industrial area in Ashbridge's Marsh and the central harbor. This will provide a great deal of work for mechanics and laborers. It is intended to have a conference with the Board of Control and City Council concerning the program early in the new year. Another suggestion is that a forward movement be inaugurated for securing new industries, as there will be abundance of electrical power available if the citizens, as they probably will do, pass the bylaw for the acquisition of the Mackenzie power interests.

---

An ingenious plan was adopted for the removal of a waterworks standpipe about twenty feet in diameter and over a hundred feet high. It was surrounded so closely by buildings that it could not be felled like a tree and to build scaffolding would have been too costly. A circular platform was built slightly smaller than the inside of the pipe with empty barrels under it to give it sufficient buoyancy to float upon the water. The pipe was pumped full to begin with and as the work proceeded the water was drawn off. A gang of men upon the floating platform had an easy job of cutting off the pipe section by section by oxy-acetylene apparatus.—Compressed Air.

---

A device has been invented by M. Lequex for regulating the temperature of electric furnaces. Briefly the device consists of a glass tube inclined at 30 deg. and connected at its upper end with a vessel containing a fluid which undergoes considerable dilatation under the influence of heat. The lower end of the tube connects with a vertical cylinder containing mercury in which is an adjustable piston. In the sloping tube, where the mercury enters up to a certain height, are spaced platinum contacts connected with points on the coil of a rheostat. The device is placed in the furnace, and when the latter is cold the platinum points are short-circuited by the mercury. The furnace therefore receives the full current. With a rise in temperature the liquid in the upper vessel expands and forces down the mercury, thus putting into circuit a succession of the various sections of the rheostat connected with the platinum points and diminishing the current.

---

It is estimated that the proposed new nurses' home at Calgary will cost $185,000. The building will be three storeys in height and of fireproof construction.

# Explosion of an Oxygen Tank

THE accompanying engravings show some of the damage done recently by the explosion of an oxygen tank. One man was killed, a considerable number of persons were more or less seriously injured, and the property loss was large.

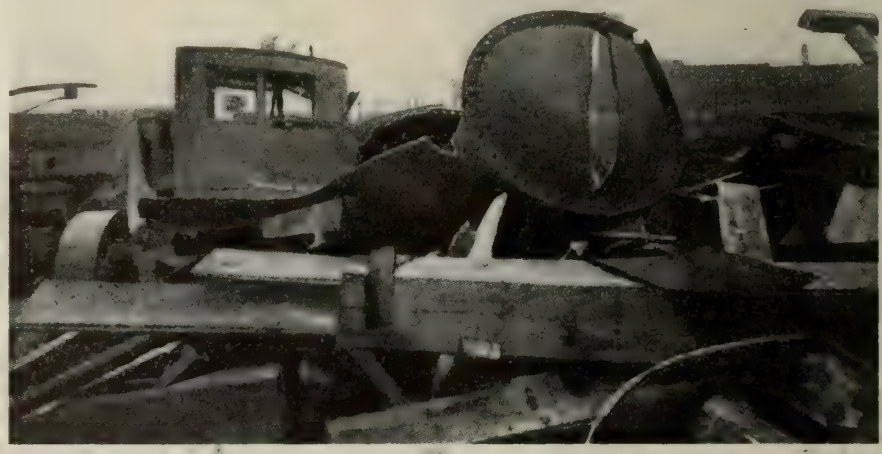

FIG. 1—EXPLODED TANK AND RUPTURED HEAD.

The tank, which was used for storing electrolytic oxygen, was about ten feet long and four feet in diameter. The shell was made of 7/16-inch plate, laid in two courses, each five feet long, and the longitudinal (or "fore-and-aft") joints were of the triple-riveted lap type, having a calculated efficiency of about 75 per cent. The upper head of the tank was convex, and the lower head was originally concave. (This method of construction is not altogether ideal, but it is reasonably safe for ordinary purposes, when a factor of safety of at least five is used by the designer.) A safety-valve was provided and adjusted to blow off at 100 pounds pressure.

The initial rupture apparently occurred in the solid plate, the line of fracture running parallel to the length of the tank, but keeping well away from the riveted joint. The shell tore away from the head at one end, and the line of rupture also followed the girth joint at the middle of the tank, so that a considerable part of one of the sheets opened out like a leaf in a book or magazine. (See Fig. 1.) In addition to this, the lower head, which was originally concave, was ruptured along one of its diameters, and its curvature was reversed so that it was convex after the accident.

The cause of the explosion is not definitely known. In connection with the

Interior View of Garlock-Walker Warehouse

## 20,000 Sq. Ft. of Floor Space Containing Every Variety of New and Used Machinery

YOU see merely a corner of our warehouse in the above illustration, but it will serve to give you an idea of the variety and extent of our line of machinery. Practically everything is found here for Woodworking and Metal-working purposes — lathes of all kinds, high speed drills, millers, planers, power hammers, electric and pneumatic tools — tools, in fact, of every description for shops large and small.

There are many used machine tools included in our exhibit, a number of them just as serviceable as new tools. It will pay you to look them over, for if they suit your purpose a considerable saving will result.

Remember this: Whether you are to personally inspect our stock or not you can place confidence in our desire and ability to furnish you with tools that will give absolutely good service. We aim to always supply our customers with machines best suited for their requirements. Success in this respect accounts for our continued and ever-growing patronage.

FIG. 3—GENERAL VIEW OF RUINS.

production of electrolytic oxygen there is always a possibility of reversal of polarity occurring in the electric generator, and a consequent mixing of oxygen and hydrogen; but it is believed that this did not occur in the present case. It is far more probable, in our opinion, that the accident was due to the presence of lubricating oil in the tank. Pumps used for compressing oxygen are supposed to be lubricated with soap, or merely with water; but it is said that distinct traces of lubricating oil were found on the lower head of this tank after the explosion. The use of any true oil for lubricating purposes in connection with the compression of oxygen is always dangerous, and it appears to be highly probable (as we have already said) that this accident was due to the presence of such oil, and to its spontaneous explosive combustion. It also appears to be more than doubtful if the gas was properly tested for purity.

The exploded tank was supposed to be strong enough to require a pressure of 1,000 pounds per square inch to produce rupture,—assuming that the pressure was applied steadily and with gradually increasing intensity. In accordance with well-known mechanical principles, however, a suddenly-applied pressure of materially less magnitude might produce failure. We have no way of knowing what the actual maximum pressure may have been.

This accident, whatever its cause may have been, illustrates the reality and seriousness of the danger associated with the handling of compressed gases, and demonstrates the need of exercising great care to keep every kind of combustible matter away from compressed oxygen,—whether the combustible material be gaseous, liquid or solid.—Travellers' Standard.

## WATER POWER AND LOCATION OF PLANT

The presence of coal has been one of the most important factors determining the industrial expansion of various countries during the past hundred years or so.

This condition is gradually changing through the exhaustion of coal supplies. A recent article by G. H. Ashley, State Geologist of Pennsylvania, emphasizing the necessity of replacing coal by water-power, is particularly significant, coming from one who is well able to judge the situation in this great coal state. His statements are of special interest to Canada in view of the prediction that industrial supremacy will, eventually, pass from coal-depleted regions to areas where large water-powers are available. It is even pointed out that one way of keeping the industries where they are in the United States would be by the importation from Canada of enormous quantities of hydro-electric energy available on the St. Lawrence and at Niagara.

Mr. Ashley holds that: "The industrial East has maintained its supremacy because of cheap fuel and nearness to markets. Because of cheap fuel Pittsburgh can afford to haul iron ore from Minnesota. It does not take a seer nor even a scientist to point out that, if our present increased use of power continues, a generation will see the exhaustion of cheap fuel in the East."

"A review of the field today shows that, in several of the districts, practically all of the thick coal has been mined out, while in others it is possible to count the years to the time when the supply will be gone. It may be argued that, as the cost of coal increases, the manufacturing interests of the East will turn to water power. That argument leads to the question of the adequacy of the water-power of that region to take over the burden now carried by coal."

"In addition to the powers within the boundaries of the northeastern United States, there are large powers to the north in Canada. The St. Lawrence below the international boundary is estimated to have a potential horse-power of nearly 1,500,000, and the provinces of Quebec and Ontario have been estimated to have a maximum of 6,000,000 h.p. each, including that from Niagara and the St. Lawrence. Already 125,000 h.p. is imported into New York from Ontario, and a small amount is imported into New England. If all of the Canadian water powers were developed and Canada would allow the exportation of, say, one-half the power, or 6,000,000 h.p., it is probable that the northeastern corner of the United States could look forward to an ultimate utilization of not less than 10,000,000 to 12,000,000 water horse-power."

It need hardly be pointed out that the benefits accruing to Canada from the exportation of 6,000,000 horsepower would be relatively negligible. One large manufacturing plant using, say, 1,200 h.p., would employ more men than the water-power plants generating 6,000,000 h.p.

---

A Hobart correspondent in the "Times Trade Supplement," says that the National Portland Cement Company, Maria Island, Tasmania, are sending their own engineer to the United Kingdom and America to select the most modern machinery. The whole of the plant for the first unit is expected to be delivered on the works within the next 12 months. It is stated by the secretary of the company that it is proposed to produce from 30,000 to 50,000 tons of cement per year with the first unit, the ultimate objective being 150,000 tons a year, which would be far in advance of the production of any other company in Australia at the present time.

---

According to a recent statement on the position of the electrical industry in Germany, the output of the German heavy cable makers for the first half of the current year is only 30 per cent. of that of the corresponding period in 1913, while estimates comparing the second halves of these two years point to a proportion of 25 per cent. only. The output in the lamp industry last year was 70 millions of which 25 per cent. were exported, though before the war the production was much greater, and the export about one-half the total output.

# OBITUARY

The death occurred in Montreal on December 31st of Paul Fitzgerald Brophy, mechanical and electrical engineer, at the Canadian Explosives Ltd.

D. J. Dickson, Sec.-Treas. of the James Wilson & Co., railway and steamship supplies, Montreal, died on New Year's day. Mr. Dickson had been with the company since coming to Montreal forty-five years ago.

Wilfred C. Sly, president, and George K. Fanner, vice-president of the W. W. Sly Foundry Co., Cleveland, were killed by bandits who after the hold-up escaped with the company's pay envelopes containing $4,200. The two men died instantly.

The death took place in Wellesley Hospital, Toronto, suddenly on Sunday of Sir Frank Baillie. He underwent an operation some weeks ago, and apparently was progressing favorably, when complications developed and the end came quickly. The late Sir Frank Baillie was president of Canadian Aeroplanes, a firm that turned out very good machines on short order. He was likewise president of Canadian Cartridge Co., Limited, Hamilton, and president of the Burlington Steel Company, Limited, Hamilton. The Canadian Cartridge Company was organized by him shortly after the commencement of the European war for the purpose of manufacturing cartridge cases for the British Government and, it will be remembered, that in June, 1916, he turned over to the government the sum of $758,248 profits from the manufacture of munitions. He was largely responsible for the organization of the Dominion Steel Foundry Company, Hamilton.

The Dominion Transportation Bldg., Welland, has been purchased by the Fulton Motors, H. O., 59 Yonge street, Toronto. No new building will be done until spring.

The contract for the construction of the drydock at Esquimalt, B.C., has been awarded to P. Lyall & Son. The tender was $4,300,000, which is about two millions less than the government estimate.

## FIRMS WANT TO ESTABLISH TRADE RELATIONS WITH CANADA

Information regarding the following lines can be obtained by communicating with this paper and mentioning key numbers.

2462. **Industrial Machinery.**—A British firm in Constantinople with extensive connections desires to receive particulars from Canadian suppliers of industrial machinery with a view to future developments of this trade.

2472. **Iron and Steel. Hardware, Tools, Handles and Canned Goods.**—Two African firms, one in Port Elizabeth and the other in East London, make requests for catalogue of any of the above or kindred lines from Canadian manufacturers prepared for regular deliveries.

2466. **Provisions and Foodstuffs, Machinery, Automobiles, Lumber.**—A firm in Cairo, Egypt, the head of which is a British subject and who claim long experience, are desirous of securing the agency of Canadian manufacturers and shippers, and articles suggested are: Provisions, condensed milk, meats, horses and cattle, salted and smoked fish, canned fruits, tobacco, and flax fibre, also agricultural and labour saving machinery, oil engines, automobiles, and lumber. Full list of articles and proposals on file at the Commercial Intelligence Branch, Dept. of Trade and Commerce, Ottawa.

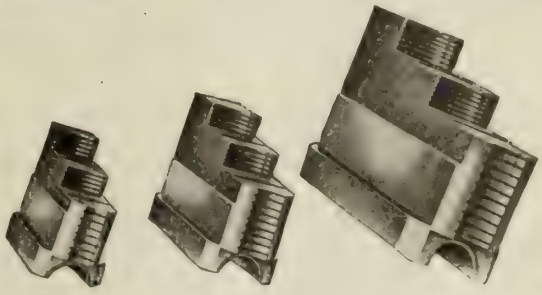
2458. **Fencing material.**—A Johannesburg firm of importers making a specialty of iron and steel fencing material request correspondence from Canadian manufacturers prepared for regular export.

2459. **Baling Wire.**—A Liverpool firm ask for quotations on baling wire, 9 foot lengths, 14 gauge and looped one end.

2460. **Industrial machinery.**—A British firm in Constantinople desires to get in touch with Canadian exporters of industrial machinery of all kinds.

2461. **Industrial machinery.** — Three large British firms in Constantinople with extensive connections are desirous of receiving particulars from Canadian suppliers of industrial machinery of all kinds with a view to the resumption of normal trade with that centre.

2454. **Gasoline and farm engines.** — A Japanese firm of agricultural implement importers in the Hokkaide is anxious to hear from Canadian manufacturers of gasoline engines. The firm is at present importing from the United States, but would be glad to give preference to Canadian manufacturers. The size most in demand is the 1 3-4 h.p. model with magneto ignition, adaptable either to gasoline or kerosene, but all sizes up to 8 or 10 h.p. are imported. Catalogues and c.i.f. prices are requested immediately.



2455. **Iron, steel and engineering specialties.**—A Canadian business man, who is representing an important Canadian manufacturing enterprise in the United Kingdom, would be glad to undertake a few additional Canadian agencies, more especially anything relating to iron, steel or engineering specialties.

*If interested tear out this page and place with letters to be answered.*

*Beatty Bros., Limited, Fergus, Ontario, with branches throughout Canada in a recent issue of their weekly sales bulletin, "Facts," give a very clear idea of the value of Hardware and Metal to the Canadian trade. This is what "Facts" has to say:—*

# "Do You Read Hardware & Metal?"

"We do not often take space in FACTS to boost any particular paper, but we are making an exception in the case of Hardware and Metal.

"If we did not know that so many of our hardware salesmen subscribed to it, we should be tempted to republish in FACTS some of their recent articles on the price situation.

"Some ten or fifteen trade papers—as distinct from farm papers—come into the FACTS editorial sanctum. There is none with half the weight and breadth of information that is possessed by Hardware and Metal.

"During the easier days of the past few months,—when the main question was not what the Sales Force could sell but what the Factory could supply—we may have been tempted to let Hardware and Metal go by the board.

"You can't afford to neglect it in these days. It is just full of authoritative information on the price situation in particular and hardware merchandising in general.

"So read it carefully. It gives you just the dope you need. When you tell the merchant that prices are not going to slump—well, he may not quite believe you. He feels you may have some axe to grind.

"But when you can quote or indicate some article in Hardware and Metal to prove your point,—it convinces.

"Remember, Hardware and Metal carries a lot of weight. It is known to be thoroughly unprejudiced and reliable. There are very few stronger trade papers in America so far as their own particular fields are concerned.

"So don't neglect your weekly reading of Hardware and Metal. Clip out any specially good points and paste them in your notebook for easy reference.

"The first two or three items on page 40 of the October 23 issue are dandies—probably you noticed them. If not, turn up your copy and read them.

"We all have to be well posted in these days or we go under. This is no time for the half-informed salesman to be on the road."

## HARDWARE AND METAL

*"Canada's National Hardware Weekly"*

**143 University Avenue, Toronto, Canada**

**Montreal Branch, Southam Building** **Winnipeg Branch, Union Trust Building**

Published every Saturday since 1888. The only weekly hardware paper in Canada and the only hardware paper in Canada that gives you a circulation statement audited by the Audit Bureau of Circulations.

# OILGAS
INDUSTRIAL FURNACES

# Lower Fuel Bills *for* The New Year

THAT'S the **Oilgas** New Year's Greeting—one of vital importance to you.

Resolve now to put your heating system on a more profitable basis. Industrial Furnaces burning **Oilgas** will cut your fuel bills in half. They are more economical than coal, producer gas, or powdered fuel.

***Furnaces for***

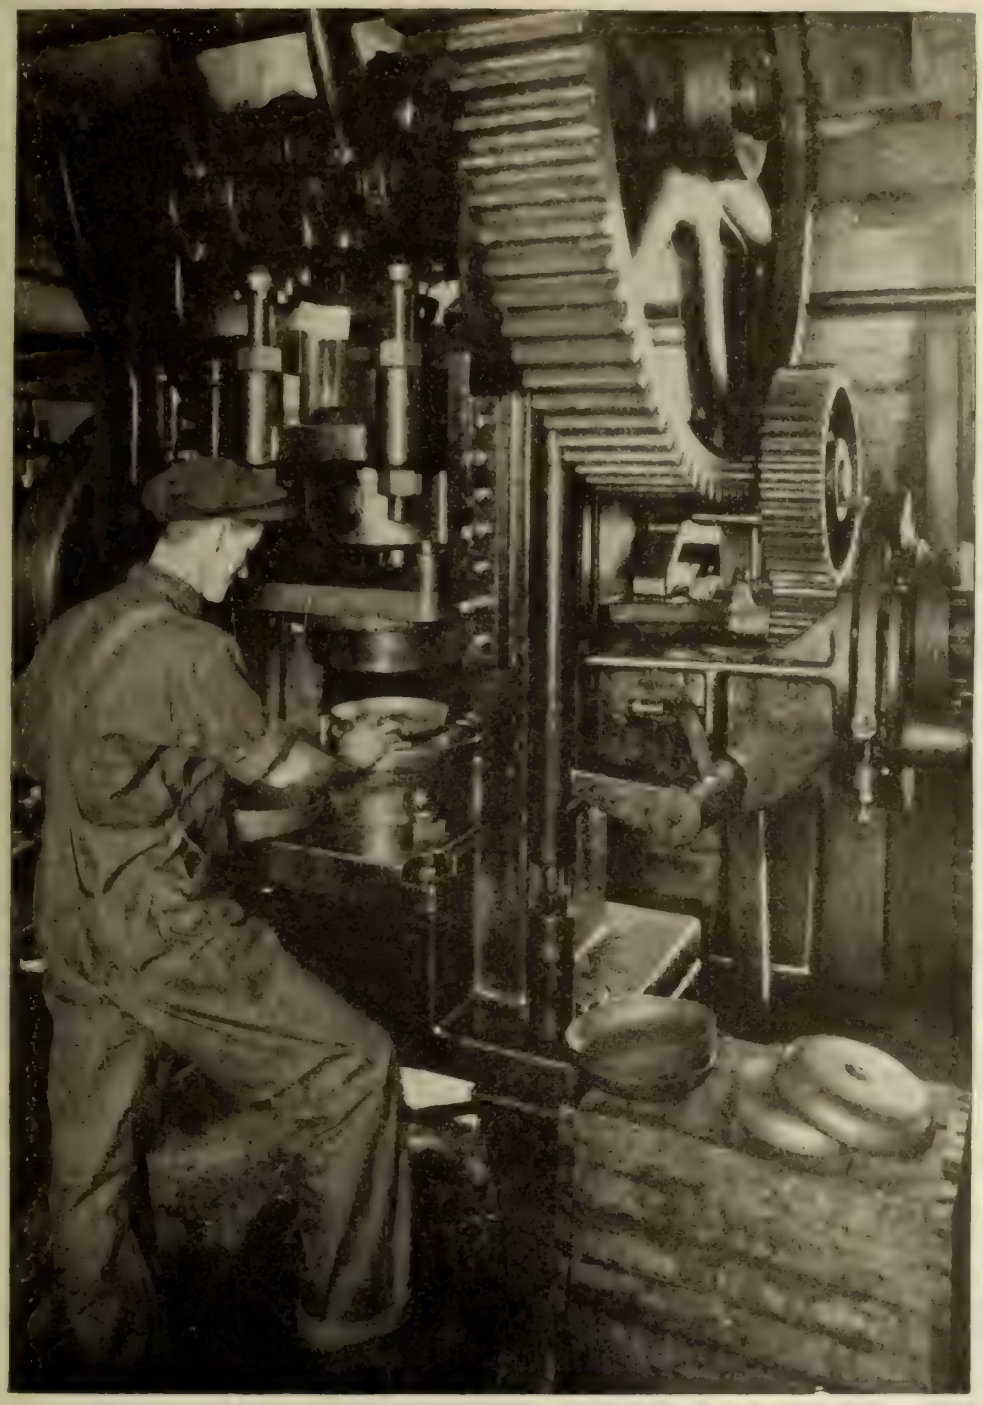
# WALTHAM
## GRINDING WHEELS

ALOWALT

CARBOWALT

## Some Interesting Facts for the Man who Grinds Cast-iron Pistons

The photograph taken at the International Motors Company (Plainfield, N.J.) shows the grinding of cast-iron pistons 4 inches diameter, 6 inches long. The total tolerance on the diameter is .001 inch. About .020" is removed in the operation. The actual grinding time is four minutes for each piston. Can you better it?



Waltham Wheels, chosen by a process of elimination during competitive tests, have been in use in this department for over eight months. The wheel used on this operation is a Waltham Carbowalt Grinding Wheel, 36 grain, Grade K, 18 inches in diameter, by 3-inch face.

What is your grinding problem? (There's one in every plant). State it—we'll guarantee to find the answer for you.

Waltham Grinding Wheels are made for all purposes. Efficient service is merely a question of finding the *right Waltham for the job*—as here.

# 1300 10-Inch Brass Gongs

is the steady day by day production rate obtained by Bevin Bros. Mfg. Co., of East Hampton, Conn., on this "BLISS" 3½-B Toggle Drawing Press.

The press was installed in 1907 and has averaged four days per week operation since that time. No parts have had to be replaced since installation, and it is in first-class condition to-day.

Besides the 10-inch gong, this same press is used, also, for drawing 6, 7, 8, and 12-inch gongs, all from ⅛-inch brass.

Bevin Bros. have over twenty "BLISS" presses in operation at present. These were installed at various times over a period of nearly twenty years.

# No. 2 TYPE "R"
# Hartness Automatic Die

***WITH SHANK FOR REVOLVING SPINDLES***

These dies are designed for use on either vertical or horizontal spindles. Die is re-locked by forward motion of sleeve, which may be actuated by a yoke working in the groove or by a fixed stop making contact with rear edge of sleeve at the return stroke. Die is unlocked in the usual manner by retarding its forward motion or by a fixed stop, making contact with the external tripping button shown on the face of the die. External tripping button is especially desirable in cutting very short threads as it relieves the thread of the strain incidental to unlocking by the pull-off device.

**The diameter of the No. 2, Type R die is 3 3-16 in., and its length as shown is 3½ in.**

**The Die cuts both right and left-hand threads ½ in. to 1 in. in diameter, and from 10 to 40 threads per inch.**

**Shanks are varied to meet individual requirements.**

**A set of standard chasers in carbon steel is supplied gratis with each Die.**

**No tools of any kind need be used in changing chasers.**

**A chaser grinding jig is supplied gratis on Die orders if desired.**

# *Boyers balk the chalker*

THE trail of perfectly-driven rivets in the wake of Boyer-equipped riveters makes rivet inspection a "light occupation" indeed! And cutting out improperly driven rivets is an expense worth avoiding.

Sustained driving power and day-in-and-day-out *dependability* is the only straight-through road to 100% steam or air-tight rivets.

Long after other hammers have been "stepped down," Boyers are still hard-hitters. Backed by the durable Boyer valve–the valve case with five lives – their giant driving power is as everlasting as the hammer itself.

The hardest-hitting, longest-lasting hammer you can buy is the *Boyer.* Ask for Bulletin 600.

# MILWAUKEE MILLING MACHINES

**Efficient on all Classes of Milling—Light and Heavy.**

MILWAUKEE Milling Machines are scientifically designed and constructed, embodying only the best obtainable materials and workmanship. Better materials give longer life and superior service. Finer workmanship means greater accuracy, and, through the mechanic's knowledge of the capabilities of his machine, time saved, and thus, larger outputs.

IN every branch of manufacturing you'll find Milwaukee Milling Machines and you'll also find that every "Milwaukee" has built an individual reputation for its ability to withstand long, hard, high-speed service. Milwaukee Milling Machines are noted for their power and ruggedness, and their accuracy and ability to handle delicate work, as well as heavy operations, is just as highly esteemed.

FIRMS that seek the certainty of milling satisfaction find their hopes realized in the "Milwaukee."

# Premier Meighen Discusses National Issues in MACLEAN'S

**The Rt. Hon. Arthur Meighen, Prime Minister of Canada, has written for January 1st MACLEAN'S a forceful exposition of his platform and policy.**

HE discusses the bi-lingual issue, the tariff, reconstruction, the growing unrest and unemployment — but he avers that the tariff is the "one great issue of our domestic politics."

"Why is it the issue?" queries Mr. Meighen. "It is the issue, I think, because the enemies of the Government cannot oppose us on any other."

Regarding the tariff, the Premier tells readers of MACLEAN'S: "We do not propose going any higher *on any single line of articles.*"

"Is Mr. Crerar hedging?" the Premier inquires.

Of Mr. Mackenzie King he says: "He can be quoted on almost every conceivable side of the tariff issue."

*Articles by Mr. W. L. Mackenzie King and Mr. T. A. Crerar will follow in succeeding issues.*

## "The Drama of Our Great Forests"

***A BIG INSTALMENT IN JANUARY 1st MACLEAN'S***

This stirring story by Arthur Heming is continued in January 1st MacLean's, chock-full of wood-lore, fascinating yarns of the luring, frozen North, and amazing tales of actual adventure. The life history of the Canadian beaver, our national animal, is unfolded in a manner that surpasses fiction, as fact so often does if truly told by a masterful writer—"the beavers—those wonderful amphibious animals of the Northland that display more intelligence, perseverance, prudence and morality than many a highly civilized human being."

## Other Big Features

**"The Big Time Man."**
By C. W. Stephens.
A romantic story of the unromantic business of making bottles.

**"Money and Motion Pictures."**

# New Method Saves Valuable Hours

### To Duplicate Blueprints

Tracing them in the drafting room takes hours — sometimes days — of a highly paid man's time, always with a chance of errors.

The PHOTOSTAT accomplishes the same result in a few minutes at a cost of a few cents and without errors.

### To Make Drawings of Small Machine Parts

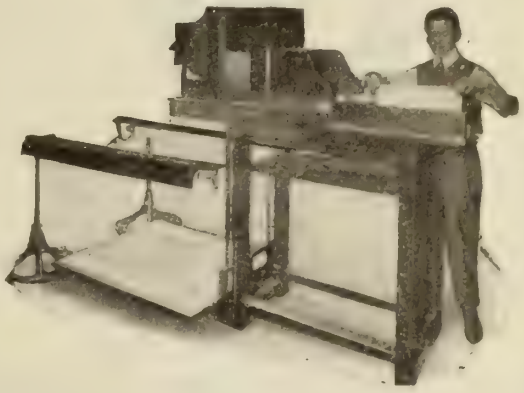
in the drafting room, costs many dollars and takes hours or days of time.

A PHOTOSTAT copy of a small machine part accomplishes the same result and is made in a few minutes at a cost of a few cents.

### To Make Advertising Layouts

by hand for six or a dozen publications requires hours of work by an expensive man.

The PHOTOSTAT quickly duplicates the original layout at the required size and as many times as desired at a cost of a few cents apiece.



### To Copy Catalog Pages

letters, reports, charts, etc., takes hours of a stenographer's time. The results cannot be exact duplicates and there are frequent errors.

The PHOTOSTAT produces an exact duplicate, without errors, in a few minutes, at a cost of a few cents.

## The PHOTOSTAT

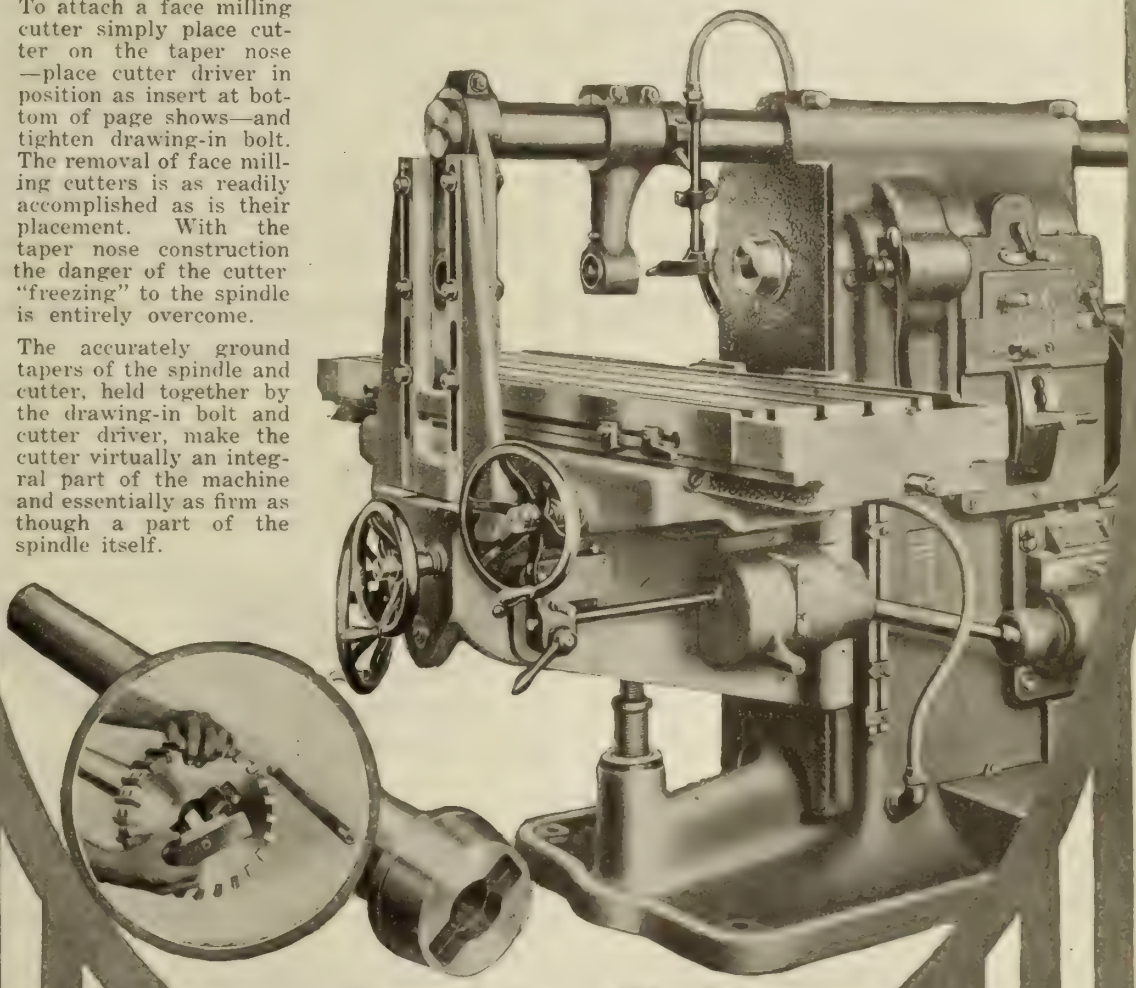
# BROWN & SHARPE

## MILLING MACHINES



### The Taper Nose Spindle

Assures a Positive Cutter Drive under all conditions. The front end of the spindle is tapered, hardened and ground and has a recess to receive cutter driver and clutch on arbors and collets.

Face milling cutters are quickly and easily removed and replaced. Note the fewness of parts, the absence of screws and loose parts.

To attach a face milling cutter simply place cutter on the taper nose—place cutter driver in position as insert at bottom of page shows—and tighten drawing-in bolt. The removal of face milling cutters is as readily accomplished as is their placement. With the taper nose construction the danger of the cutter "freezing" to the spindle is entirely overcome.

The accurately ground tapers of the spindle and cutter, held together by the drawing-in bolt and cutter driver, make the cutter virtually an integral part of the machine and essentially as firm as though a part of the spindle itself.

# UNION DRAWN STEEL CO. LTD.

Manufacturers of

**Bright Finished Steel Shafting and Shapes.**

Large stock of all sizes.

***Send for Price List***

HAMILTON, ONTARIO

# SPECIAL MACHINERY

## Built to Order

Also gauges, punches, jigs, dies, small tools, etc.
Prompt Service.
Moderate cost.
Send Blueprints for estimate.

MADE IN BR·EN·CO CANADA

**Brown Engineering Corporation**
LIMITED, TORONTO
415-419 King St., W. Tel. Adel 425

# CURTIS

Sales Offices: Coristine Building.
UNITED STATES
Factories and General Offices: Jersey City, N.J., U.S.A.
Branches in Principal Cities of the United States and in Foreign Countries.

# Greaves-Etchells Electric Furnace

FURNACES FOR EVERY PURPOSE

**Electric Furnace Construction Co.**
908 Chestnut Street Phila., Pa.

McKenzie Saw Table

# A New and Better SAW TABLE

***Saves Time and Space***

This New McKenzie Saw Table has several outstanding features which make it the best machine of its kind to buy. Does the same work as machines of larger dimensions, costs less, takes up less space and produces work faster. It is 23½″ x 30″. Distance from saw to ripping fence is 13″. Floor space 30″ x 36″. Furnished with belt, ripping fence, two mitre fences and 9″ saw.

Specially suitable for pattern shops, technical and manual training schools. **Write for prices and full particulars.**

## THE D. McKENZIE MACHINE CO.

GUELPH, ONT.

# YOU'LL FIND WHAT YOU WANT

In the Classified Advertising Section of Canadian Machinery. Look on pages 106-107 for all kinds of new and used machinery.

**YOU MAY WANT WHAT YOU FIND.**

*If what you need is not advertised, consult our Buyers' Directory and write advertisers listed under proper heading.*

# Says a Reader of Many Years Standing:

"I do feel that your paper is the most interesting and readable financial journal published in this country and, perhaps, in the entire North American Continent. Each week I somehow find time to read every word of it—mostly in bed, late at night. I find I have to read THE FINANCIAL POST in order to maintain myself properly abreast with the bigger things and movements taking place in this country."

THE FINANCIAL POST is published for men who are interested in big things—not necessarily men who personally have big financial interests at stake, but for men who are eager to know what is happening that will have a bearing on business and the well-being of Canada generally.

THE entire editorial organization of the MacLean Publishing Company is at hand to co-operate with the editors of THE FINANCIAL POST. Specialists in many businesses write for THE POST. A practical farmer, in constant touch with the farming conditions, deals with crop prospects.

THE POST is a paper edited by specialists for business specialists.

# The Financial Post

MONTREAL

Subscription Price per year (52 Issues) $5.00

# Canadian Machinery BUYERS DIRECTORY

**If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index—last page of book, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.**

FOUNDRY
GALT, ONT.

# Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

## If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

***We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.***

# HENDEYS *the only lathes in this tool room*

The results which a machine gives in actual operation is its greatest proof of merit.

Such are the results which the Saginaw Products Co., a division of the General Motors Corp., secure from Hendey Lathes that they use no lathe but these 39 Hendeys in their tool room!

Many are the firms which Hendey Lathes have impressed with their superiority for quality production with minimum costs for maintenance and operation. Let their reputation be a guide to you when considering the installation of lathes.

**The Hendey Machine Company**

# Reaches Anywhere

**General Purpose Oiler**

Made with steel spring bottom, in three sizes—No. 1, 1/3 pint; No. 2, ½ pint, and No. 3, 1 pint. A 7" spout to each.

**Combination Filler and Funnel**

For Hardware Stores, Garages, etc., in four sizes No. 101, 1 pint and 10" spout; No. 102, 1 quart and 13" spout; No. 103, ½ gal. and 13" spout; No. 104, 1 gal. and 13" spout.

**R. R. Oiler**

For Locomotive, Machinery, Threshers etc. In two sizes No. 4, 1 pint and 10" spout; No. 5, 1 quart and 11" spout.

**Oil Gun (No. 201)**

For Automobile and all types of machinery, Fitted with a 9-inch spout.

## Why the All-way Oiler Sells

The All-Way Oiler reaches anywhere by means of a flexible spout that may be bent to suit any place that must be reached. In using the ordinary oiler much oil is lost in attempting to reach awkwardly situated oil holes. The saving of oil from this feature reduces oil bills 50%. All-way Oilers have a special cleaning device at the end of the spout which insures their being always ready for use.

BROWN AND SHARPE

MACHINISTS'

TOOLS

Thoroughly dependable tools for the mechanic and manufacturer

# SMALL TOOLS

## Pratt & Whitney Adjustable Blade Reamers

These reamers have eccentric relief and can be set to size without regrinding. They are unexcelled for design and simplicity and ease of adjustment.

The eccentrically relieved blades are stronger than others, do not chatter, and produce a smoother hole. The hand, shell and fluted chucking reamers have interchangeable nuts, screws and wrenches. The bottom of a hole can readily be faced.

By a simple adjustment of the blades the reamer can easily be set to size, without regrinding.

*Prompt service is assured at our nearest store, where P. & W. Small Tools are carried in stock for immediate delivery. Place your order there to-day.*

*If interested tear out this page and place with letters to be answered.*

Boyer Valves not only withstand severe service --they bear the brunt of untold abuse, proved by the *purposely* distorted Boyer Valve shown below. By means of four sizes of "over-size" Boyer Valves every Boyer Valve case has *five* lives —another Boyer-economy feature.

Low upkeep costs prove the Boyer three-unit-part design logical, simple, dependable. Each part is *separately* renewable and interchangeable, with hammers of a like type. Result—sustained working life, maximum service from each unit part,

# *Back-up your production with Boyers*

"BACKING-UP" your operators and riveting operations with Boyer Pneumatic Tools is a dependable step towards securing air and steam-tight jobs at lowest cost per rivet driven.

Slightly cooled rivets work no hardship on the operator or great driving power of Boyer Riveting Hammers.

Power *required* is power *delivered* with Boyers. They waste neither air-power through leakage nor man-power through excessive vibration.

Workmen do more and earn more with Boyers. Secure a Boyer on trial from stock at the Branch nearest you listed below and *prove* it.

# The "Coventry" Chuck

*Below are shown one Standard and one Special application of the "Coventry Chuck"*

Standard reversible jaws set for gripping irregular or eccentric work. The gas engine cam is made from a mild steel stamping with 3-inch hole drilled into solid metal. The chuck is our 15-inch size. After the jaws have been properly set, work like this is gripped and chucked as easily as any circular object and much quicker than if a four-jaw chuck were used.

The Coventry Chuck used as a face plate fixture, the object in this instance being clamped back on a locating ring, and a stem fitting into the bore of the chuck. The clamps are held from the T slots in the jaw slides. The chuck here is used for a second operation on the part shown at the left. Use of the chuck in this way saves the trouble and time of taking it off and putting on a special face plate fixture.

## Adaptability

In addition to being exceptionally strong, the "Coventry" Concentric Chuck is also adaptable to a large variety of special work which is outside the scope of standard self-centering chuck. The exceptionally long bearing surfaces of the jaw slides permit the use of a wide range of special jaws.

These can readily be made by the user, no expensive scroll cutting apparatus being required; the only special tool necessary is a hob, which we carry in stock. The standard soft jaws can be shaped to suit irregular work, thus frequently saving the cost of special fixtures.

**Let the "Coventry" Chuck solve your chucking problems.**

***Write for Bulletin No. 308.***

**Made in 6 Sizes: 9 in., 12 in., 15 in., 18 in., 21 in. and 25 in. diameter**

# THE JOHNSON FRICTION CLUTCH

## Put Johnson Clutches on Your Machines

The tight and loose pulley is passing from favor. With all its disadvantages, it long survived because a reliable friction clutch was not in evidence.

But in the Johnson Clutch, builders of high grade machinery have found a real clutch service. It has been thoroughly tested and adopted on the finest machines made.

Replace your tight and loose pulleys with Johnson Clutches.

*Single Clutch with Pulley Mounted*

**Write for our Yellow Catalog and Booklet, "Clutches As Applied To Machine Building."**

# TYPE "R"

## HARTNESS AUTOMATIC DIES

### FOR REVOLVING SPINDLES

The No. 4 Type R Hartness Automatic Die has been designed for use on revolving spindles, either Vertical or Horizontal.

### THREE TYPES OF CONTROLS

Outside button coming into contact with some set stop on the machine.

Regular knock-off by carriage coming to a stop while chasers, which are carried along by the revolving thread, pull the body away from the latch pin.

Sleeve control enable chasers to be released or locked at any time.

**The Hartness Automatic Dies are the only automatic dies made that will, without the aid of lead screws, cut threads rivaling in lead accuracy those cut by the best engine lathes.**

# Sixty-four operations with one set-up of the work—

The job referred to is a typical LANDIS achievement—a striking example of the saving of time and labor which is possible with the LANDIS Boring, Milling and Drilling Machines.

The job requires in all sixty-four distinct operations, including boring, milling, drilling and tapping. One set-up of the work—a heavy piece—is all that is required on the LANDIS.

Versatility is a strong feature of the LANDIS. Wherever installed, it is always busy. Ask us for full details on this profitable machine.

*Why not learn the full details?*

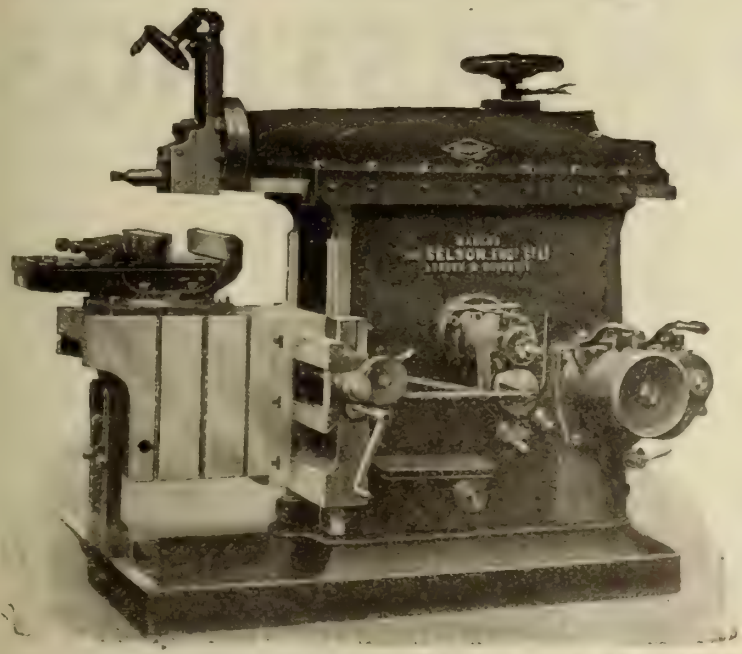
# MURCHEY SOLID ADJUSTABLE TAPS

## Solid Adjustable Taps Cost Less

Unlike the solid trap, the Murchey Adjustable does not have to be scrapped when the cutting edge is worn.

**It is much less expensive to buy a new set of chasers than to buy a new solid tap.** And the difference in price is saved with every set of chasers you purchase! This is why Murchey Solid Adjustable Taps cost less money.

Murchey Adjustable Taps will do the same work, with the same accuracy, as the best solid tap. We are ready to prove to **you** that this Murchey tool will do **your** work the way you want it done, and at less cost than by the use of a solid tap.



**Try this tool on your work, at our expense.**
**Write to-day.**

# WHY THE "SNAP" *in a* SNAP GAGE

THE meaning of the word "snap" as applied to limit gages of this type refers primarily to the way in which the gage is used when inspecting cylindrical work. Owing to the extra large tool steel gaging plugs with their beveled edges, this snap is especially evident when the inspector is using a Johansson Adjustable Limit Snap Gage. An operator only has to operate a Johansson Gage for a short time in order to appreciate how nicely it snaps over the work.

"SNAP" Number two is a most valuable one and applies to the breaking of the cast-iron gage frame. Johansson Snap Gages will not bend, warp, or spring if they are dropped. Instead, the cast iron will snap—the operator thus being prevented from using a gage which is inaccurate and passing spoiled work which would cause untold damage later on.

THE "snap" which perhaps appeals the most to the user of a Johansson Limit Gage of this type is represented by the slang meaning of the word. It is undeniably a "snap" to set, to maintain the accuracy and to use a Johansson Snap Gage. When it becomes necessary to reset the size on the Go and No Go plugs, this can be easily done by means of the adjusting screws which are securely held in their correct position by the action of the clamping screws which force the plugs to seat securely against the adjusting screws. The accuracy is then insured permanent by the sealing wax placed over the adjusting screws.

NOT only does the insulated grip protect the gage from change in size owing to temperature, but it also makes the use of the gage, hour after hour a "snap," for its location is such that the gage is always nicely balanced when so properly held.

IN short, it is a "snap" to manufacture by the limit system when Johansson Gages are used. Why not let them prove it in your own shop?

# Robertson Process Metal

## *For Economical Replacement*

Corrugated iron roofing and siding require frequent painting and repairs. The result is excessive maintenance costs. Robertson Process Metal, however, does NOT need frequent painting and repairs. Used for roofing, siding and other building purposes *in the first place*, it keeps *down* the cost of up-keep. Used for replacement, it provides insurance against future loss through premature depreciation, owing to its resistance to rust and corrosion.

Unusually strong and permanent, Robertson Process Metal is also light in weight. It insures lower transportation costs. It can be erected with speed and economy. It is the most economical permanent building material because it saves in FIRST COST and MAINTENANCE COST.

You can see and feel an actual sample of Robertson Process Metal. A piece of the metal, as illustrated, together with interesting literature, will be sent upon request.

## METAL FOR ROOFING AND SIDING

What's the decimal equivalent of 19/32nd's?

What is the breaking stress of No. 11 Roebling Wire?

How shall I select a bevel gear cutter for this work?

What clearance should I allow in grinding a milling cutter?

Answers to such common problems are found in the Starrett Data Book for Machinists.

Tables of decimal equivalents, machine screw dimensions, tapers and angles, wire gage standards — and hundreds of other facts in every-day use, are included in its 180 pages.

You'll find that it fits your job as it fits your tool kit. Its pocket size lets you keep it handy for ready reference. And there are mighty few problems that aren't answered in the Starrett Data Book.

At your hardware dealers. Also ask for Catalog No. 22 "3."

The City of
# ST. JOHNS
QUEBEC

## Locate in this Real Transportation Centre

St. Johns is a nerve centre of the network of railways connecting Central and Western Canada with the Maritime Provinces and with the Eastern States. Seven railways, including the C.P.R. and G.T.R., run through the city and are interconnected in the St. Johns yards by a terminal switching company. The manufacturer locating in St. Johns enjoys the advantages of competitive freight rates and dispatch in the assembling of raw materials and distribution of the finished product. The city in fact commands lower freight rates and a cheaper coal supply than any other centrally located manufacturing city on the North American continent.

St. Johns is directly connected by rail with the Montreal docks, 27 miles distant, affording first-class facilities for foreign trade. The city is an ideal location for the American manufacturer opening a branch plant in Canada; having direct connections by water with New York, the St. Lawrence and Great Lakes and the Eastern Seaboard of the United States.

Unlimited electric power is developed at Chambly, eleven miles north-east of the city, and distributed at prices that will compete with any city or town in the Dominion.

Cheap living conditions and low rents and taxes have resulted in cheap labor and an abundant supply of both skilled and unskilled workers is always available. Labor troubles are quite unknown.

In addition to the natural advantages of St. Johns as an industrial site the city also offers extraordinary inducements, such as: Tax exemptions; street extensions; bonus of five per cent. on your payroll for five years, making it an unusual industrial opportunity.

*Without a knowledge of your business or the conditions affecting it, we do not claim that St. Johns is rationally your location; but we know that St. Johns possesses extraordinary advantages, that in all probability it is the best site for your plant from every point of view, that you will be running the risk of serious mistake if you do not include this city in your investigations.*

*Seven railroads, includ... Canada's great transc... tinental lines.*
*Finest ocean shipping ... cilities.*
*Canal connections w... New York, the East... States, and the Gr... Lakes.*
*Cheapest labor market ... Canada.*
*Plentiful supply of sk... ed and unskilled labor*
*Cheap and abundant el... tric power.*
*Cheap coal and lo... freight rates.*
*Desirable factory s... with all public conve... ences immediately av... able.*

# DOMINION GRINDING WHEELS

***Test These Wheels on YOUR Work!***

Made in Canada, in our own factories, from the raw product to the finished wheel.

Canadians are beginning to realize the importance of buying at home so long as they can secure quality. We don't want to sell you Dominion Wheels merely because they are made in Canada. All we ask is that you test them against any wheels you are now using their merit will speak for itself.

The standard quality of Dominion Wheels is secured by manufacturing our own abrasive material. Thus we know the grade and grain of every wheel.

# GRINDING TRACTOR LINKS

The modern grinding wheel is of tremendous importance in placing the tractor on the market.

Before the tractor reaches the farmer in its finished efficient state it must go through many processes of manufacture. There is practically no part of the finished tractor which the grinding wheel has not touched.

By this means of machining, millions of abrasive grains are placed in compact form and with each revolution of the wheel, the grains are brought into action and become cutting tools.

The result is rapid production with exactness.

ALUNDUM wheels have been proving their excellence on these many operations. For grinding caterpillar links of manganese steel regular Alundum wheels 24x3x2", ¾ inch taper per foot both sides, grain 10, grade T, have done remarkable work.

# 15 Sales Offices Backed by the 100% Standard of Quality

THE Canadian Fairbanks-Morse Company Limited reaches out to you through its sales houses and offers the service and satisfaction that is assured by its 100% standard of quality and service.

To be able to turn to an institution that dominates its field in the industrial world is to safeguard the character of the merchandise you buy. To deal with an organizationthat is doing business at your very door puts upon the man you know that "responsibility which is the conscience of business."

Every one of these 15 offices has been established to bring to you the full advantages and benefit that have made The Canadian Fairbanks-Morse Co. Limited a national institution. Here in these offices is offered everything mechanical that your business requires — they centralize your purchasing—group your orders—bulk your shipments and send but one invoice. And when you buy from The Canadian Fairbanks-Morse Co. Limited you are guaranteed the 100% standard of quality and service in product and organization.

Make our nearest office your buying centre—our catalogue is your buying guide —our 100% quality seal your guarantee.

CANADIAN MACHINERY
AND
MANUFACTURING NEWS

VOL. XXV. No. 2 January 13, 1921

# *Training the Machinist of the Future*

Practical jobs are tackled, not mere display parts. Outside work is often accomplished, and a small bench miller and several drill presses have been made by the students.

*By J. H. MOORE*

A PARTIAL VIEW OF MACHINE SHOP.

WHERE will the machinists of the next ten or twenty years come from? Were we to say "from the schools," that would hardly be correct, but if we say, "a great percentage will come from our technical schools," we would be on safe ground. There is, unfortunately, a popular misunderstanding as to the character of technical education. Some think of it merely as training of the hand and that such a school is a good place to send a backward child to. This is an erroneous impression, for the technical school is no dumping ground for stupid children. A walk through any technical school will convince the most skeptical on this point. Here will be seen clear-eyed, keen-witted boys, men in the making, boys who have decided on this method of developing their ability for the particular trade they desire.

A certain amount of book work is required of all pupils preparing for trades. No one can be a skilful worker in any trade without some instruction in mathematics and elementary science, therefore stupid children, or shall we say, backward children, would not make good at such a school. First, they must have planted in them the elementary seeds of knowledge.

Realizing the splendid work such schools are doing throughout the country, Canadian Machinery decided to study first hand one of these institutions. The Hamilton Technical & Art School was visited, and the story to follow will describe the conditions found there, touching especially on the machine shop and kindred trades, as it is in these we are most interested.

The present factory unit of this school was erected in 1918-1919, and was occupied for the organization of classes in September, 1919. Previous to that date, the school was run on a much smaller scale, and in a different part of the city. The demand, however, for technical education became so great that a six-foot plot was bought on Wentworth street, and the first unit erected. The building plan adopted provides for an extension to the present building that will cost in the neighborhood of $600,000. Even after this addition is made, the school will still have a very large athletic field for their students.

The number of pupils in attendance has increased amazingly during the last

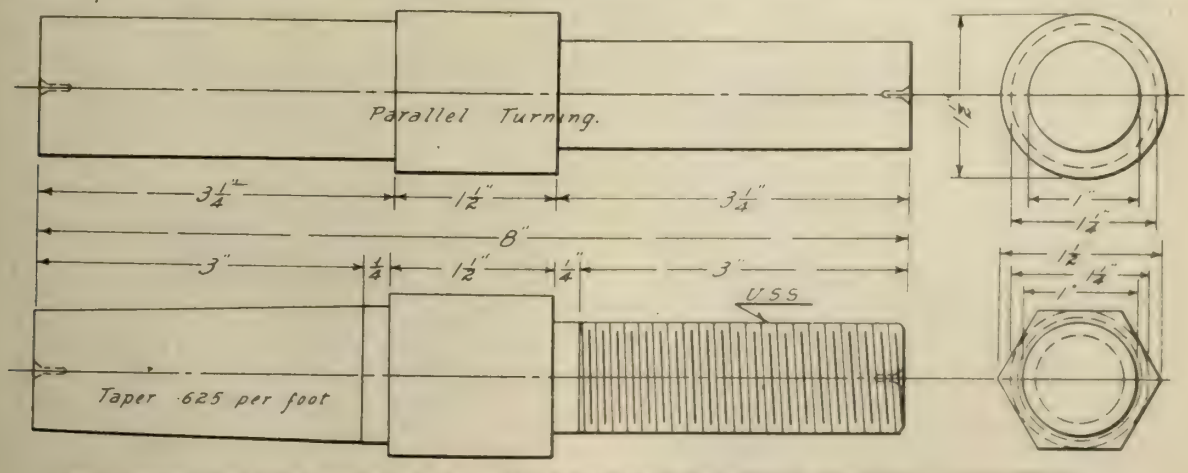

FIG. 1—THIS CAST IRON SPINDLE IS SPECIALLY DESIGNED TO EMBODY PRACTICAL OPERATIONS.

A PARTIAL VIEW OF PATTERN MAKING DEPARTMENT.

A CORNER OF THE ELECTRICAL DEPARTMENT.

four years. The attendance this year taxes the capacity of the present building, both in the day time and evening. During the day over 600 pupils attend, and in the evenings 5,407 students have enrolled. The records show that they have an average attendance every evening of 418. This figure was taken in October and has increased since then.

### Subjects Taught

The evening classes cover over fifty courses of instruction, and a staff of over 80 teach 120 evening classes each week. Briefly, here are the subjects covered, these being subdivided into first, second and third year studies, if deemed advisable:

Arithmetic, Telegraphy, Electricity, Pattern-making, General Woodworking, Cabinet Making, Advanced Carpentry, Stationary Engineering, Printing, Linotype Operation, Shop Sketching and Mathematics, Machine Drawing, both elementary and advanced; Architectural Drawing, Chemistry, Machine Shop Practice, Tool and Die Making, Oxy-Welding, Motor Mechanics, Applied Mechanics, Commercial French, Commercial Spanish, Structural Design, Cooking, Sheet Metal Drafting, Millinery, Plain Sewing, Dressmaking, Freehand Drawing, Lettering and Show Card Writing, Clay Modelling, China Painting and Design, Perspective Drawing and Water and Oil Painting.

### Day Courses

The day courses are naturally wider in scope, as the pupil has more time to study the various subjects. The course in which we are interested is the general industrial course, covering four years. Pupils of the junior fourth book standing in the public schools are admitted to this course, the second year of which leads to high school entrance standing. Upon completing the second year pupils have the option of continuing the industrial course, with special trade training, or of entering the technical high school course.

The first two years of this course not only prepares the student for entrance standing, but at the same time offers opportunity for training in carpentry, cabinet making, pattern making, machine operation, tool and die making, practical electrical work, motor mechanics, electro-plating, printing, mechanical and architectural drawing, and machine shop practice.

The work accomplished at this school is of an extremely practical nature. During 1919-1920, forty pupils were placed as apprentices to various trades. Twenty concerns in the city send their apprentices for a certain length of time each week, so that they can, through technical training, eventually become more valuable men.

We will not go into detail on the other subjects being taught, as after all, the machine shop is what we are chiefly interested in.

### The Machine Shop

Keeping in mind that each student attends school from 9 a.m. to 12 a.m. and from 1.30 p.m. to 4.30 p.m., let us see how he spends his time. Owing to the number of subjects he must cover, his work is subdivided into short periods on each subject. The schedule is so arranged that in addition to covering all the academic subjects, he spends 1½ hours each week in each of the trade rooms, such as printing, electrical, drafting room, machine shop, etc. In this way every student has a chance of covering the various trades. This arrangement goes on for two years, when the student must then make up his mind to specialize in some particular trade, or proceed with the high school course, if he is desirous of going to the university, rather than following a trade.

### The First Year's Work

The method of procedure was thoroughly discussed by the author and head instructor, F. H. Kirkpatrick, and, in as far as possible, the following subjects are covered in the first year:

Bench work is subdivided into six sections, hammer and chisel, files stamps, centering, calipers and hacksaw The drill press work covers two divisions first, drilling holes under ½" diameter and second, countersinking holes fo wood screws. In the first year worl all speeds and feeds are adjusted b the instructor in charge.

Next comes the lathe. This is di vided into five subjects, viz., facing chamfering, straight turning, roughin cuts, taper turning, and simple threa cutting.

The milling machine work is divide into three sections, viz., plain millin using the vise; plain milling, using th centres, and simple indexing. Shape work is classed in two sections, surfac

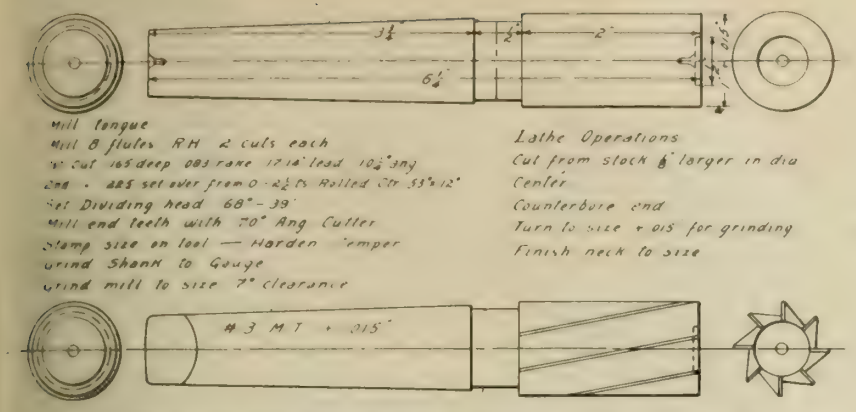

FIG. 4—HERE WE SEE THE VARIOUS INSTRUCTIONS ON THE MAKING OF A 1" SPIRAL END MILL.

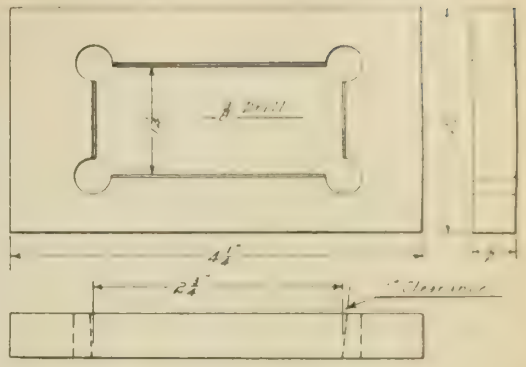

FIG. 3—THIS PAGE FORM BLOCK GIVES THE STUDENT LOTS OF PRACTICAL WORK

ing (roughing cut), and surfacing to a finished cut.

### Second Year Work

In second year subjects a review of the first year studies is always given. After this is completed the following further steps are taken. On bench work the student receives instruction on lay-outs, scraping, grinding drills, how to use a speed indicator, and determine his various speeds.

The drill press work is carried on up to holes 1¼" diameter, this meaning that they have to lay out the holes, watching their pop marks. The holes must be accurately drilled, and close check is kept on the students to see they have the right use of the chisel in correcting holes which are inclined to run. After the drilling come lessons in reaming.

The lathe work deals with parting, turning for drive, shrink and running fits, chuckwork, and crowning. Further instruction on the miller is given, this including the uses of the endmill, and problems in spur gear cutting. The shaper work is also advanced, parting, end cutting and down cutting being performed. These subjects are taken up, in addition to the review of the first year's work as already mentioned.

### Third Year Work

Taking it for granted that the student has now decided to follow up the machine tool trade, he is allowed to specialize on this trade, devoting more time to it, and eliminating from his studies such trades as printing, etc. In all third year work a review of both first and second year is given.

The bench work goes still further into detail. The uses of taps and dies are found by actual experience. Hand-reaming, elementary die work, hardening and tempering are next taken up.

On the drill press lessons are given on boring, using the boring bar and power feeds. Next comes counterboring, drilling to a layout, also cylindrical work.

The lathe work receives careful attention, the student being trained to turn correctly to shoulders, taper turning to gauges, turning, using the steady rest, cutting multiple threads, and all conditions of chuckwork such as boring, reaming, taper boring and inside thread cutting. Next comes knurling and eccentric turning.

Milling machine work advances very rapidly in this year, rack cutting, milling tee slots, cutting bevel gears, cam cutting, spiral cutting, and the cutting of worm gears being done. On the shaper the student learns to cut keyways and all types of angles. The fourth and last year he advances still further into machine shop practice, even to the building of bench milling machines, hand punch presses and drill presses. The tools are by no means models. They are practical machine tools made from proven designs and in fact are marketed by the school. Ten drill presses have so far been sold and are in use in various machine shops, proving very satisfactory.

### Practical Work

From the drop of the hat, so to speak, the student is taught to work on practical pieces, not display parts. Every job he performs contains real lessons in machine shop work. He is never wasting his time, for the course has been mapped out by practical men, who have passed through the mill themselves.

It is a great feeling to find that theory is given second place, and that practice with a capital P is given the seat of honor. As the instructor put it, "Boys are a peculiar problem. They must have something of real interest to them, yet you must not step them up too quickly if you want to make real tradesmen of them. We have no hard and fast rule regarding how fast a boy may advance. It is strictly up to the boy himself. We have a standard course. It's up to the boy to get through the course as promptly and efficiently as he can."

### The Use of Tables

It has been found to be splendid policy to provide students with tables for

GENERAL VIEW OF CHEMICAL LABORATORY.

THE BOYS DELVE INTO THE ART OF PRINTING IN THIS DEPARTMENT

their use, these sometimes taking the shape of blueprints, while in other cases they are printed in their own printing shop. These tables include such subjects as reading the micrometer, allowance for running and force fits, points for twist drill users, cutting speeds for high speed steel, laying out angles, turning tapers, operating an engine lathe, and so on. These tables are printed on good stock, and made of a standard size, suitable for filing. The boys take advantage of this fact on many occasions and always have at a moment's notice a set of handy references.

Before leaving the subject of the table form of instruction, let us quote a portion of what the table entitled "operating an engine lathe" has to say: "An engine lathe," says the pamphlet, "is an ordinary form of lathe fitted with a lead screw and power feed." The student is then asked to locate the following parts:

Bed, headstock, tailstock, tailstock base, carriage, apron, saddle, compound rest, cross slide, tool post, lead screw, feed rod cone pulley, faceplate, headstock spindle, tailstock spindle, live centre, dead centre, back gear, driving gear, the ways, stud gear, reverse lever, feed rack, feed clutch and split nut lever. After the student has looked these parts over he should be well able to at least talk intelligently regarding the names of the parts. The other parts of the lathe, including chuck, rest, etc., are then discussed.

Next come the instructions, "Never make adjustments to the machine while running. Never tighten two clutches at once, such as the feed clutch and the split nut, which is used only when cutting a thread."

"Never lean against a machine while it is running. The hand may slip against a moving part and be injured, or the clothing may be caught.

"Oil every moving part daily. See that oil holes are not filled with dirt. Wipe off all excess oil. A well oiled machine indicates a careful mechanic."

The operator should now learn to operate first by hand and then automatically, the longitudinal and cross feeds, reversing each; how to use the back gears, leadscrew and compound rest; how to clamp tailstock and tailstock spindle; how to secure high and low speeds.

We will not go into any further detail regarding these instructions. Enough to say that all statements are simple, clear and concise. In fact, there are many truths included that tradesman could take to heart.

### An Actual Job

Let us consider the cast iron spindle shown at Fig. 1. This spindle is so designed that the student who completes it successfully has mastered, in no small measure, the fundamental principles of lathe practice. He is given a blue print as shown, and proceeds as follows:

The piece is first centered, and a test made to see that centres are correct. The centre hole is next made on the drill press. Having proceeded thus far the piece is taken to the lathe and rough turned to 1-16" oversize. The ends are next faced to exact length, after which the shoulders are squared to length.

The next step is to rough and finish turn to blue print size. The taper is now turned on the end, this being done by the following process. The small end is turned to its proper diameter, after which the tailstock is set over enough to cut the desired taper. The formula, length of taper, multiplied by taper per foot is used. The thread is now cut on the front portion.

Next comes the milling of the hexagon, this being made to a special gauge nut. The six sides are milled, and the formula, 1.155 × flats=diameter, is used.

### The Next Step

When the student has completed this part he, in a way, advances still further with the same piece. Fig. 2 illustrates what he does in this case.

He rough and finish turns to the smaller sizes shown, also squaring the different shoulders to the blue print size. He next turns the No. 3 Morse taper to a gauge, using the following formula:

$$\frac{\sqrt{\text{of W} \times \text{T per ft.}}}{2} = \text{S. O.}$$

After this is completed he proceeds

### TEN SAFETY COMMANDMENTS

1. Thou shalt have no thoughts other than thy work.
2. Thou shalt take no unnecessary risks nor try to show off nor play practical jokes, for by thy carelessness thou mayest do injury which will have effect upon the third or fourth generation.
3. Thou shalt not swear nor lose thy temper, when things do not come just right.
4. Thou shalt not clean machinery while it is in motion.
5. Remember that thou art not the only one on the job and that other lives are just as important as thine own.
6. Honor thy job as thyself, that thy days may be long in employment.
7. Thou shalt not watch thy neighbor's work, but attend to thine own.
8. Thou shalt not let the sleeves of thy shirt hang loose nor the flaps of thy coat unbuttoned, as they may get caught in the machinery.
9. Thou shalt not throw matches or greasy waste on the floor nor scatter oil around bearings, as a dirty worker is also a clumsy worker and a clumsy worker is a menace to his fellow workers.
10. Thou shalt not interfere with the switches, nor the cables, nor the engines, nor anything else that thou art told is dangerous.

---

An ounce of prevention is worth a pound of cure.

Every man's task is his life preserver.

To live long it is necessary to live carefully.

Doing nothing is an apprenticeship to doing wrong.

### POINTS FOR TWIST DRILL USERS

If the drill chips on the edge it indicates that the lip clearance is too great and fails to support the cutting edge. This may be because the drill is too hard. It is advisable to ease off on the feed and watch the grinding.

If it splits in the web, it is either ground with improper centre lip angle or the feed is altogether too heavy. The centre lip should be at about 45 degrees to the cutting lips of the drill. The drill is in best condition when the chip comes out in a close coil.

If the outer corners wear it shows that the speed is too high and it should be reduced. This is particularly noticeable in drilling cast iron.

Drilling cast iron can be done at a little faster speed than for steel, but the corners must be watched.

### ALLOWANCES FOR RUNNING AND FORCE FITS

| RUNNING FITS | | FORCE FITS | |
|---|---|---|---|
| Diam. of Bearing | Diam. of Shaft | Diam of Hole | Diam. of Shaft |
| 1 | .999 | 1 | 1.001 |
| 2 | 1.998 | 2 | 2.003 |
| 3 | 2.997 | 3 | 3.005 |
| 4 | 3.9965 | 4 | 4.006 |
| 5 | 4.9963 | 5 | 5.007 |
| 6 | 5.996 | 6 | 6.008 |
| 7 | 6.9958 | 7 | 7.0085 |
| 8 | 7.9958 | 8 | 8.009 |
| 9 | 8.9957 | 9 | 9.01 |
| 10 | 9.9956 | 10 | 10.0105 |
| 11 | 10.9955 | 11 | 11.011 |
| 12 | 11.9954 | 12 | 12.0115 |
| 13 | 12.9953 | 13 | 13.012 |
| 14 | 13.9952 | 14 | 14.013 |
| 15 | 14.9951 | 15 | 15.014 |
| 16 | 15.995 | 16 | 16.0145 |
| 17 | 16.9949 | 17 | 17.015 |
| 18 | 17.9948 | 18 | 18.0155 |
| 19 | 18.9947 | 19 | 19.016 |
| 20 | 19.9945 | 20 | 20.017 |

Allowances for Drive Fits are one-half that of Force Fits.

to cut the thread. The last step is the cutting of the teeth on the centre portion of the spindle. From the foregoing description it will be noted that the student has received real practical tuition during the making of this piece.

### Another Example

Another good example of work is that shown at Fig. 3. This, on the face of it, looks like a very simple proposition, but note the various fundamental principles involved as the operations proceed. This piece is what is known as a 16-page form block, and is used in the printing department of the school for tuition purposes. Thus a double purpose is served, viz., a good practical job, that can be used elsewhere.

This piece starts off on the shaper, and the top surface is rough cut, also the edges. The next step is to rough and finish the bottom surface, after which the top surface receives a finish cut.

The piece is now taken to the milling machine, where the edges are milled parallel, and to the blue print size. Special care is taken to see that the edges are square with the face of the block. One end is now milled square to the faces and the edges.

### Bench Work

The block is next taken to the bench, where it is marked off by means of the square, scale and scriber. The end is now chipped by hammer and chisel to within 1-64″ of the marked line. It is next filed to the line, making sure the filed surface is square with the faces and edges.

### TURNING TAPERS BY SETTING OVER THE TAIL STOCK

Tapers are usually given in "inches per foot" and include the total taper or difference in diameters unless otherwise noted. In turning tapers in the lathe it is necessary to consider the total length of the bar, whether the taper extends the whole distance or not, and to set the tail stock over just as though the taper extended the whole length.

If the taper is ¾ inch per foot as in pipe threads and the whole bar is 16 inches long, then the total taper is 1 inch and the tail stock must be set over ½ inch. There is nothing to remember except to set the tail stock over half the total amount if the whole bar was tapered at the same rate.

The top surface is now scraped, using a surface plate to ensure proper accuracy. The block is next laid out, and the centre located. To allow students to become familiar with the use of the surface gauge, this instrument, in conjunction with the surface plate, is used.

The rectangular form, as shown in sketch, is now laid out, the dividers, scale, scriber, square and hermaphrodite calipers being the tools used. The ⅜″ corner clearance holes are next laid out, also the ¼″ holes inside, and tangent to the rectangular layout, and tangent to one another.

### Drill Press

The drill press is next used, when the ⅜″ and ¼″ holes are drilled. From here it goes back to the bench again and the webs are drifted out, and then the rough edge is chipped fine. Filing is next in order. First the edge of hole is rough filed, after which a smooth file is used to file to finish mark lines and square with the face. The last step is to file a one degree clearance on the edge of hole. A protractor is used to ensure accuracy.

It will be readily seen that this plan would not be adopted in an actual machine shop for the production of such pieces, but by arranging the steps in this manner the students get familiar with the use of the various tools, at the same time deriving considerable machine shop experience. No poor work is allowed to pass. For example, suppose a student is rather careless in the filing operation. Does he get away with it? Not much. He must start all over again and produce a block that is correct in every detail.

### Making An End Mill

We could go on indefinitely, quoting examples of work done, but for the purposes of this article, will take up only one other job in detail. The sketch shown at Fig. 4 illustrates, in reduced form, the style of blue print used in the making of a 1″ spiral end mill. As will be noted, all instructions are contained on the blueprint. The student can, by this method, go right through the job, feeling confident he is pursuing the right tactics.

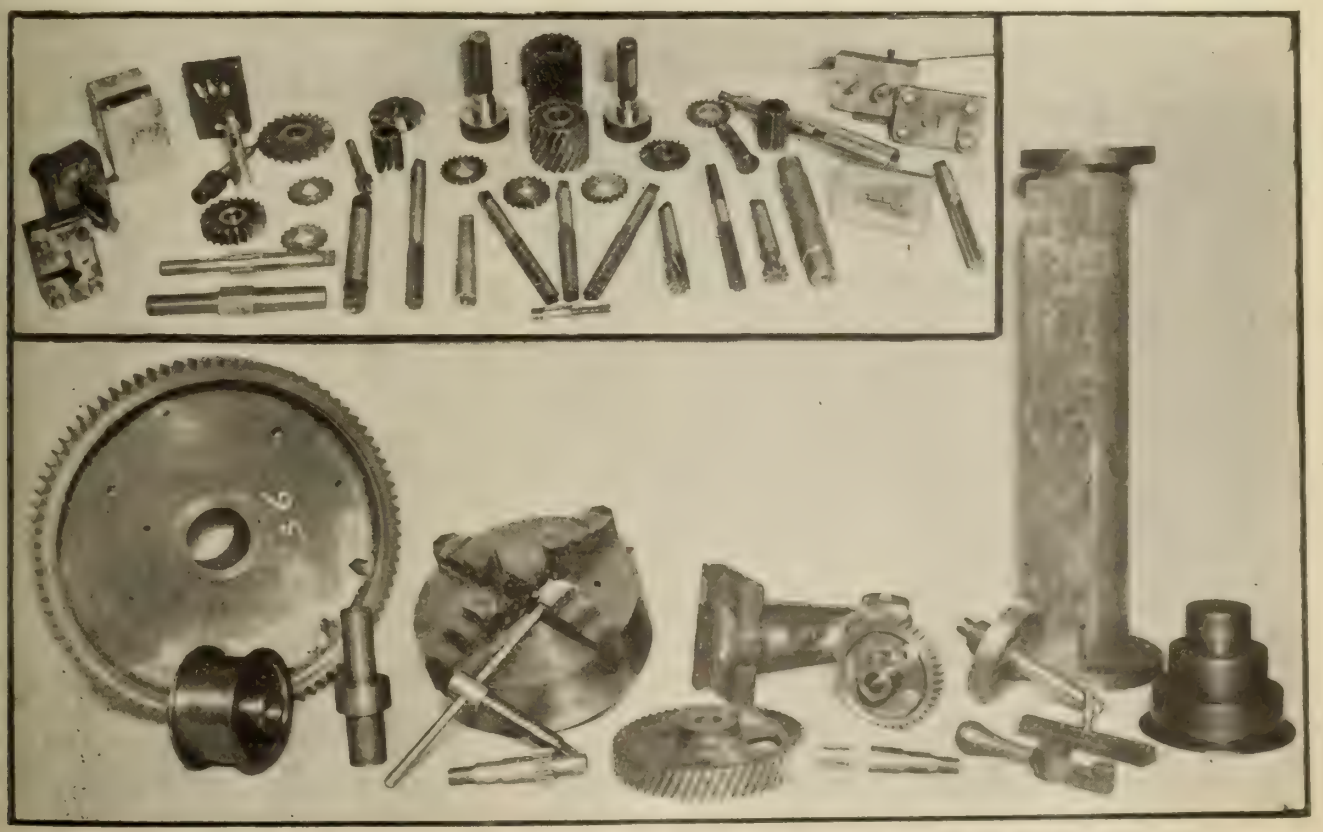

FIG. 5 LOWER VIEW: SHOWING A VARIED ASSORTMENT OF WORK COMPLETED.
FIG. 6 UPPER VIEW: A MISCELLAUEOUS GROUP OF SMALL TOOLS, SOCKETS, DIES, AS MADE BY THE BOYS

### Examples of Finished Work

To illustrate the variety of work accomplished, let us refer to Fig. 5. Here are shown several articles, which have been completed by the students, some of which are what is termed outside work. By outside work we mean work completed for some outside firm. Many concerns take advantage of this chance, and send in work to be finished, paying the school for the same. In this way the school is partially self supporting. The chuck shown is only one of many that have been completed by the students, and the writer inspected the same and found it to be excellent workmanship.

One would hardly believe that such accurate work could be done by boys. The tall casting to the right of the photograph is part of the column for the drill press mentioned earlier in the article. The cutting of gear teeth is something in which the boys excel, and the four examples shown in the photograph bear out this assertion.

Fig. 6 depicts a few of the small tools, gauges and dies produced by the students. In this group is shown the spindle we already referred to in the first example of lathe work. Note the small, three section, armature field die in the background, also the key blank die to the right. A great majority of the cutters used by the students are made by themselves. This statement holds equally true regarding sockets, arbors, reamers, end mills, taps, gauges, form cutters, drills, etc. In other words, the idea behind the tuition is to make the students capable of producing almost any tool or fixture needed. Nothing is purchased outside, except absolutely necessary.

### Die Press

Take for example Fig. 7. Here we see a die press, or in other words, a hand punch press. This machine was made by the boys themselves and is not a show machine by any means. The instructor can be seen in the foreground, while one of the full time boys (as he is called) is shown in the background. While on the subject of this young fellow, let us tell a little of his ambitions. The author purposely got him talking. "What's your idea in staying here all day long?" I asked. "In order to make myself a real mechanic," came back the reply. "Before coming here I was apprentice at ——— plant, but could not get the chance I wanted, so I saved up my money with the object in mind of coming here as soon as I had sufficient to keep me. As soon as I had enough I came here, and since that time I've had a real chance. I work on every machine in the department, get the best of instruction, and hope to be a real mechanic in the near future."

Judging from the way he spoke, and his confident bearing, I think he'll get his wish. When I was interviewing him I noted he was working on a special die for an outside concern. This die was by no means simple, but our young friend was getting along admirably.

### Equipment Used

The very nature of the work performed speaks well for the equipment used. The very latest machine tools are in evidence. The lathes are of the modern type, the planers and shapers of the best obtainable design, in fact every machine tool is a late model. The boys are not asked to perform wonders on some old machine that probably came from the ark, but get even better machines to work on than they might get at first, if learning their trade elsewhere. The line shafting is cleverly arranged, being driven by three separate motors, thus allowing the running of only such machines as necessary.

### Examples of Tables

To illustrate a few of the tables used for instruction purposes, let us refer to Figs. 8, 9 and 10. No. 8 describes all that is essential, while No. 9 is a very handy table for reference purposes. No. 10 soon tells the student the causes of poor drilling. Fig. 11 is nothing more or less than a warning notice, yet is gotten up in a nice style to attract the boys' attention. The remaining views of the school are simply general views taken for the purpose of showing a few of the trade departments.

"What do you think of the future for these boys?" I asked. The reply was not long in coming. "To my mind," said the head instructor, "we give a boy a training equal to any machine shop. It is of course up to the lad himself, but providing he has followed up our course from beginning to end, in an earnest manner, there is no reason why he should not become an excellent mechanic. You know," he concluded humorously, "we need good mechanics," and I agreed with him.

This is one of the machines made by the boys themselves. Mr. Kilpatrick, the head instructor, is shown in foreground, while the lad we speak of in our story is looking on attentively.

## GIANT ELECTRIC POWER STATION

The new electric power station at Glasgow, Scotland, takes rank as one of the largest in the country. It is designed for an ultimate capacity of over a quarter of a million horse power, and each generating unit—of which there are five in the first half of the station recently completed—will be of 24,000 horsepower. Each boiler is capable of producing 62,000 pounds of steam in an hour. All the latest labor-saving devices for loading coal into the bunkers, stoking the furnaces, and removing the ashes are installed, and a very high degree of economy in the production of electricity on a large scale is assured.

## NEW HOIST CATALOGUE

The Wright Manufacturing Company, of Lisbon, Ohio., manufacturers of high-speed hoists, screws and differential blocks, and steel trolleys, have just issued an attractive new catalogue descriptive of their line. It contains much data of use to those interested in hoists and a portion of the catalogue is devoted to a discussion of the various types of hoists and the field of usefulness of each.

# *Interest in Your Work an Absolute Necessity*

*By G. L. SPRAGUE, Principal Hamilton Technical School*

MODERN manufacturing methods have broken down standards in the machinist trades. Only in the tool room and repair departments are found men who could classify as all-round machinists. The rank and file of men operating machines in what is known as the metal trades are merely machine tenders, operators, and specialists, according to the mastery they possess in producing on some particular machine.

Increasing subdivision of labor in modern industry is responsible for this breaking down of trade standards. Manufacturing methods of today tend largely toward mass production. The output of the individual is only a part of the whole. His contribution is merged into that of the mass. His daily output travels to the assembling or fitting-up department. What the individual creates out of raw material rarely shows up before him as a finished product.

### Effect of Mass Production

The effect of mass production upon the individual is both mental and economic. On the psychological side his mind is dulled by montonous repetition of a limited performance of tasks. His mental capacity is not taxed, his initiative remains undeveloped, and he slumps into a condition of ambitionless effort. He goes to his day's work because it is necessary for him to earn the wherewithal to live and maintain those dependent upon him. As far as interest in his work is concerned, there is little to appeal to the average worker of this class. Work should be varied, should test a man's capacity for performance to enlist his interest. Men who have such work to do never suffer from labor unrest. Work to them is a natural function in which they find satisfaction and happiness. Economically, workers of this class are limited to opportunity for employment. They constitute the floating labor of to-day. They are not skilled, and they are not unskilled.

### What Can Be Done?

The problem is, what can, and what should be done, to revolutionize modern manufacturing methods, so that not only the physical, but also the mental capacity of men may contribute in the largest degree to industrial prosperity, and to the economic independence of workers.

To my mind apprenticeship should be established upon a modern basis. A term of four years in the machinist trade is sufficient to train young men in various operations and processes of the trade. Wages should be adequate to enable young men to live. They should be adjusted on a scale increasing every six months during the apprenticeship period, with a bonus granted upon the satisfactory completion of the course. Employers should keep faith with apprentices and assure them real training in all branches of the trade, not simply use them as cheap labor. For this purpose, in large plants apprentice shop instructors should be employed to change apprentices progressively from one class of work and machines to another. Instruction should be given one, or two half days each week in related mathematics and drawing, so that apprentices may master shop calculations and understand blue prints, also be able to make intelligible sketches of machines and machine parts. From apprentices so trained, employers could recruit efficient leaders in production.

The second step that is practicable, and should be attempted, is to establish a training department in machine operation in every large manufacturing plant. At the present time, breaking in of new men is left to the foreman, with a resultant increased scrap heap. How much the scrap heap costs modern manufacturing concerns, only their cost accounting systems will show. The cost of this scrap heap can be reduced, both to the good of modern industrial enterprises and the workers.

How is it now? A man wants a job. He applies for work, is asked if he can run a milling machine. He picked up what he could in odd moments from the other man about running a milling machine. Consequently, when in quest of work and the opening comes, he makes a bluff at running a milling machine. The foreman discovers that he is bluffing when some of his work is marked for the scrap heap.

Why should not large manufacturing plants have a shop fitted with machinery for training men, later turning them into the shops for more important work? Intensive training methods could be adopted which would provide the necessary supply.

### Rotation of Tasks

If apprenticeship training is seriously undertaken, and the special suggested training department put into operation, it would be possible in time to establish a rotation of tasks. This would give men that diversity which is the spice of life, an important factor psychologically in promoting satisfaction with work. By a gradual process of transfer from one class of work to another, output would not be seriously decreased, nor production costs increased.

G. L. SPRAGUE

THE students of the Hamilton Technical School are fortunate in having for their principal a man of such wide experience as Mr. Sprague. Previous to guiding the destinies of the youth of Hamilton he held the following positions:

He was general superintendent of apprentices for the American Locomotive Company, and was on the staff of the Vice-President of Manufacturing and Engineering. He organized the shop apprenticeship system of that company in 1910 for seven different plants.

He also held the position of efficiency engineer of the State Board of Public Affairs, Madison, Wisconsin, and made investigation of all departments of the State in 1912.

While in Madison he acted as assistant to State Board of Industrial Education and helped develop Continuation Schools in various cities. He also was superintendent of A. E. Norton Company Structural Steel Plant, Boonton, N.J.

From there he went to be special agent for the U.S. Commission on Industrial Relations at Washington, D.C., and acted as expert on industrial education and administration of child labor laws.

He was next executive secretary of the Public Education and Child Labor Association of Pennsylvania with office in Philadelphia. One year after accepting the above position, he came to Canada to take charge of the development of technical education in Hamilton, August, 1916. Since that time he has built the school to a point of high efficiency.

# Increasing the Capacity of Old Locomotives

## The Rebuilding of Old Type Locomotives—Points to Watch—How to Change Wheel Arrangement—Locomotives Having Outside Valve Gears Have Capacity and Economy Increased

By C. B. SMITH

IN these days of the high cost of railroading, responsible officers of the mechanical departments realize that the necessity for reducing the cost of all locomotive operation and maintenance is more urgent than ever. Such saving can be accomplished in two ways, one by using new and modern locomotives, the other by rebuilding old types.

The purchase of new locomotives is usually confined to the largest units permissible for each type required, and they are equipped with superheaters and other modern devices as selected by the purchaser. Older engines of modern type, but not originally supplied with superheaters, are also being so equipped at general shoppings of these engines on the greater number of the roads of the country, and as rapidly as local conditions will permit. This improvement brings the older locomotives up to the capacity of those more recently purchased, and such reconstruction will undoubtedly be continued until all such locomotives have been modernized. The wisdom and economy of this work are known to all.

On the majority of our roads there are still locomotives of the earlier modern types whose general features of construction are satisfactory, and which only require modernizing to make them economical transportation units. Improvements for such classes of locomotives may include, in addition to superheaters, piston valves in place of slide valves, outside valve gears in place of Stephenson motion, and such other improvements as are usually made upon engines at general shoppings.

### A Problem

The replacement or betterment of the older locomotives "in kind" is becoming more of a problem where suburban and local passenger service and branch-line traffic still require the maintenance of the lighter types of locomotives that can handle such traffic. Such engines are periodically returned to the shops for repairs, and the frequency of these shoppings could be reduced and mileage between them increased if the time were taken at one shopping to modernize them. Extensive reconstruction, however, requires a longer shopping period and reduces the number of engines available for road service.

In an excellent paper presented at the Convention of the American Railroad Association last June, G. M. Basford convincingly sets forth the present situation of the railroads. His paper furnishes a strong incentive for making a closer analysis of the conditions of our roads, and developing the greatest program that can possibly be carried out in rehabilitating existing locomotives.

Items which are to be considered in any program for increasing locomotive capacity are:

1. Superheater.
2. Pyrometers.
3. Brick arch.
4. Valve motion.
5. Mechanical stoker.
6. Power reverse gear.
7. Automatic fire door.
8. Feedwater heater.
9. Improvements in boiler design when new boilers are required.
10. Improved boiler circulation.
11. Increasing firebox heating surface.
12. Flexible staybolts — breakage zones.
13. Covering steam pipes.
14. Flange oilers.
15. Automatic driving-box wedges on heavy locomotives.
16. Steam-pipe joints at smokebox.
17. Pneumatic bellringer.
18. Chime whistle on freight — more audible to train crew.

These items are numbered for convenient reference and do not necessarily indicate the order of importance.

Factors which will increase the capacity of a locomotive may do so directly or indirectly, singly or in connection with others. When setting out to rebuild a locomotive the experienced supervisor appreciates the opportunity to apply many devices and facilities which will standardize the engine in accordance with the railroad company's practice, and in so doing reduce repairs and stores department expense in maintenance.

The aggregate of such improvements results in a locomotive which in proportion to its capacity will produce service results comparable with those of entirely modern construction, and at a cost approximately one-half that for a new locomtive of similar capacity. The difficulty in carrying forward an extensive reconstruction program, however, is in finding the shop facilities either on the railroad or among the locomotive builders in order to advance the work at a satisfactory rate of progress. Nevertheless, despite this difficulty the results which could be obtained from the operation of reconstructed locomotives, if they could all be rebuilt within the next few years, would than three years to complete the work, it would seem necessary to arrange for enlargement of shop facilities in order to hasten the reconstruction. If, however, adequate shopping facilities are not forthcoming, the improvement program for locomotives must be confined chiefly to the application of superheaters and the substitution of piston for side valves; together with the minor but relatively important betterments that may usually be applied at the shopping period. On some roads this work alone will require six years at the present rate to equip what can rightly be called the "early-modern" locomotives.

Some of the engines built within the past ten years have developed weaknesses in frames and in parts of running gear. It has proved justifiable to reconstruct them by substituting new parts of stronger design and thus avoid recurring breakages which interrupt both the road service of these engines and the repairs to others. On roads whose traffic and service conditions now demand and will continue to demand the use of light locomotives for passenger trains and freight trains on branch lines, the better classes of the light locomotives should also receive their share of improvements along with the heavier power.

Old locomotives requiring new boilers have very generally been scrapped, but where light train service demands no heavier engines than formerly, the writer believes it advisable to rebuild such engines with radial-stay boilers, superheaters, new piston-valve cylinders, main frames when necessary, and outside valve gears. If there is to be no increase in the boiler pressure over that formerly carried by the locomotive and the valve motion has given little trouble by breakages, the Stephenson motion may be connected to the piston valves through the usual rocker-shaft connections.

### Changing the Type

Old locomotives that are unsatisfactory as to wheel arrangement may be rebuilt and changed to another type and service. One road has converted 2-8-0 type or Consolidation locomotives to 0-8-0 switching service by removing the leading truck, applying a new boiler, new cylinders, outside valve gear, power reverse gear, and modifying the frames as required. The boiler was located to properly balance the engine. The use of the running gear and many of the parts of the original locomotive doubtless justifies such extensive reconstruction work where additional switching locomotives are needed.

The old eight-wheeled, American-type locomotives having crown-bar boilers

# Fuels, Their Uses and Proper Application

## Steel Cannot Be Successfully Treated in a Coal Forge—Properly Designed Furnace is Essential—Be Careful to Use Proper Type of Furnace—Select Your Fuel With Care

By W. A. EHLERS*, Industrial Engineer, American Gas Association, New York

THE science of metal treating is unquestionably one of the most interesting and important subjects in the mechanical field to-day, and one which calls for the most careful and comprehensive study and application if correct results are to be secured.

Metal treating has come into greater prominence in recent years, due in a large measure to the ever-increasing demand for lighter, yet stronger and more durable moving parts in all forms of machinery subjected to unusual wear or shock, and also on account of the great development in automatic and special machinery.

Unfortunately many shops are still treating tool steel in the old blacksmith forge, which is as much a relic of the "dark ages" as the ox cart is in the field of rapid transit. Steel cannot be successfully treated in the coal forge, due principally to the condition of uneven heating. Uneven heating produces uneven cooling, which in turn produces uneven stresses in the piece when it is quenched, and hence will shorten the life of the finished part.

A uniform temperature throughout the entire heated area is necessary if correct results are to be obtained. It is surprising to find that many practical steel treaters continue to use the old and crude method in treating expensive steel, because they do not see the wisdom of purchasing modern furnace equipment, which will give better results and greater economy by prolonging the usefulness of the tool.

It is of interest to note that many of the manufacturers of so-called "special steels" for tool making purposes recommend that they be heat treated in gas-fired furnaces.

Certain fundamental conditions enter into the processes of metal treating which are of great importance. One of these is the necessity for obtaining uniform results, and the elimination of the possibility of producing work below the required standard. To obtain uniform results it is very necessary to regulate and maintain the temperature of the furnace within a reasonable degree of that required for the particular operation. This imposes the condition that the fuel must be of such nature that the amount of heat delivered can be changed very quickly. It is also necessary to have positive control of the furnace atmosphere.

The ideal furnace is one which maintains an evenly distributed heat throughout the parts to be heated when loaded to its capacity, and one in which the temperature and combustion products are under positive control.

From chemistry we learn that matter may be defined as that which occupies space; that matter is composed of infinitely small particles known as molecules. Molecules are again composed of atoms, and these combine to form elements or compounds. Thus, like atoms will form an element, and when combined with atoms of other substances they form a compound.

It has also been proven by experience that the molecules of all matter are never at rest, but are always in motion and the motion of these molecules produces heat, therefore the greater the activity of the molecules, the greater will be the amount of heat produced, all other things remaining unchanged.

Moreover each combustible substance has a definite temperature of ignition and when certain of these molecules reach the temperature of ignition they have a great affinity for oxygen. The resulting chemical union between these atoms gives rise to what we term combustion. Combustion has therefore been defined as "the phenomena produced on the surface when two substances unite to give light and heat."

In a further study of combustion there are certain fundamental factors and conditions to be met if proper combustion is to be obtained and the resulting heat properly applied. All fuels are made up of combustible substances, each giving a certain definite temperature of ignition and each forming a new compound when mixed with the proper amount of oxygen at the point of ignition. This leads to the conclusion that perfect or complete combustion can take place only when these substances are mixed with oxygen in the proper proportion. Or, stated in more familiar terms, a definite amount of air is required to completely burn a given quantity of fuel.

The properly-designed furnace is an important factor in heat treating. Time will not permit me to go into this very important subject. Poorly designed furnaces are not only uneconomical but they are largely responsible for unsatisfactory results. Many furnaces are operated without knowledge of the composition of the furnace atmosphere; with no control of the air supply or flue gases. There are certain fundamental principles such as type of construction, kind of fuel and the means of utilizing the heat of combustion that govern the design, but in general the character of the work to be performed, the kind and quantity of materials to be treated are the controlling factors. The real test of a furnace for a given operation is "the variation in temperature in all parts of the furnace around the mass to be heated when the chamber is loaded to full capacity."

### Type of Fuel Necessary

One of the first things to be considered in the proper heat treatment of metals is the kind of fuel necessary to produce the character of heat best suited for the particular operation. Unfortunately there is a prevailing belief among many that when it is desired to heat-treat a piece of steel the only thing necessary is to build a fire and plunge the material into it. If results are not forthcoming they blame the steel perhaps and not the method, which, in most instances, is the real cause.

For all practical purposes fuels may be classified into solid, liquid and gaseous. It must be remembered that in the case of solid and liquid fuels each must first be converted into gas before combustion really takes place, and for this reason they are not so easily adapted to exact furnace conditions and temperature control.

Of the solid fuels, coal and coke are principally used. Lump coal and coke are not very well suited for metal treating operations, except in very large furnaces for pack annealing and case hardening in large quantities. Even with these it is not easy to maintain a uniform temperature, and there is great danger of overheating. At best they are very wasteful of fuel, and it is difficult to control the products of combustion, which is particularly essential where the metal is subjected to the direct action of the flame.

Powdered coal has a great advantage over lump coal or coke in that it may be termed a "one stage" combustion, being complete and free from residual carbon. It burns directly to $CO_2$ without the attending losses of unburned carbon and carbon contained in the ash. Its chief advantage, however, lies in the mechanical preparation of it, as it must be crushed, thoroughly dried and stored, also in the harmful action of the ash upon furnace walls and linings.

Liquid fuels generally exist in the form of kerosene, gasoline, and fuel oil. Owing to the great demand for kerosene and gasolene for internal combustion engine and other purposes, their cost has advanced to such a point that they

*Presented before the American Society for Steel Treating.

cannot be considered for the heating of furnaces. Fuel oil as a general rule is more expensive to use than coal or coke, but its superiority of these fuels in its form of application to the furnace is sufficient to overcome the increased cost. Fuel oil is a by-product of crude oil refining, and its cheapness in the past has been due principally to crude methods in refining and an over production of crude oil. With the increasing demand for motor fuel, improvements have been made in refining methods, which have very materially reduced the fuel oil available for metallurgical purposes. This situation is largely responsible for the scarcity of fuel oil and the unprecedented high price, and according to reliable authority, including the U. S. Bureau of Mines, very little hope is given that it will be any cheaper for some time to come.

A good grade of fuel oil will range from 18,500 to 20,500 B.t.u.'s per pound, and a vaporizing point of about 170° F. Considering that air is composed of 20.7 parts oxygen and 79.3 parts nitrogen, one pound at 62° F. occupies a space of 13,141 cubic feet, and at 100° F. one pound occupies 14,096 cubic feet. Theoretically it requires about 14 pounds of air to give perfect combustion of one pound of oil. Therefore it will require 14×14.096 or 197.34 cubic feet of air to burn one pound of oil at 100° F. However, in practice, it requires from 17 to 20 pounds of air, or in round figures 2,000 cubic feet of air at 100° F. to completely burn one gallon of fuel oil.

### Oil Must be Atomized

In admitting oil to the combustion chamber of the furnace it must be broken up into a fine spray, commonly spoken of as atomized, by means of a suitable burner. Atomization may be obtained in one of three ways: Live steam, compressed air, and mechanical process. Of these compressed air is more generally used.

Where air is used for atomization it is usually found to vary in pressure from 1½ pounds to 60 pounds per square inch, depending upon the kind of burner used. The majority of installations work with an air pressure of about 20 pounds per square inch. This, however, is higher than necessary for good results. With air under pressure of 20 pounds per square in and oil at 100° F. there is required about 50 cubic feet of air per pound of oil.

Steam for atomizing is not so generally used in industrial operations, due perhaps to its greater cost over compressed air. Moreover in many places it is not available. According to Durand, 0.4 pounds of steam are required per pound of oil. This agrees closely with some investigations reported to the American Society of Mechanical Engineers (August 1911 Bulletin) which give an average of 0.5 pounds per pound of oil. The latter is perhaps a safer figure to use.

### POINTS TO REMEMBER

Uneven heating produces uneven cooling. This in turn produces uneven stresses in the piece when quenched. Such procedure shortens the life of the piece.

Poorly designed furnaces are not only uneconomical, but are largely responsible for unsatisfactory results.

Powdered coal has a distinct advantage over lump coal or coke because it is free from residual carbon.

It requires 2,000 cubic feet of air at 100 degrees Fahr. to completely burn one gallon of fuel oil.

Fuel oil often contains a small percentage of water which lowers its heating value. For each one per cent. of water the heating value is reduced 13.14 B.t.u.'s Thus for an oil having nominally a heating value of 18,500 B.t.u.'s per pound and containing 10 per cent. water the heating value is reduced to 16,518 B.t.u.'s, or a loss of 1,982 B.t.u.'s. If water is in the oil, combustion is incomplete, the violet flame never appears, but the end of the flame will be dark red and fringed with smoke.

Fuel oil being rich in hydrocarbons gives a very high heat for a comparatively small volume of oil. For this reason it is particularly adaptable to heavy forging work such as drop forging, the heating of heavy bars and rods for forging and upsetting. It is also a very excellent fuel for welding.

But there are many things which must be considered before selecting oil as a fuel, particularly on the purely heat-treating operations. There is the necessity for a large and expensive storage tank which must be buried in the ground. This tank frequently leaks and much oil is wasted before the leak is discovered. Smoke, grease and the roar of burners under high pressure are serious objections, and these are not conducive to making the surroundings pleasant for the shop men.

Moreover the use of oil does not permit of automatic temperature control by placing a thermovalve in the fuel line. Conditions affecting a continuous supply are not the best, and frequently much time is lost waiting for a new supply.

Gases which are most generally used for fuel purposes are natural gas and the manufactured gases such as coal gas, coke oven gas, water gas and producer gas. These gases are preeminently suitable for and by far the most satisfactory fuel for metal treating processes. These facts combined with the economic advantage makes gas the coming fuel of the future.

Gaseous fuel is economical because it can be applied in a way most adaptable to the requirements of the material to be heat treated. Other fuels as a rule must be burned in the furnace in a certain fixed way, there is very little flexibility in their application. Gas on the other hand can be applied in a way that will give the best results with the least waste of fuel.

By its nature and composition gas offers the greatest advantage from a purely scientific point of view. It is easy to thoroughly mix it with the proper amount of air for complete combustion. With other fuels this is impossible. Control of the air-gas ratio means a higher rate of combustion, a relatively higher flame temperature, and therefore a higher thermal efficiency.

The cheapest fuel, even with other things being equal, is not necessarily the one which gives the greatest number of B.t.u.'s per unit of cost, but the one which costs less per unit of production. Numerous examples can be given to prove this statement. However, one or two should be sufficient. In a certain town in the state of New York, gas selling at a rate of approximately one dollar per thousand cubic feet replaced soft coal at about five dollars per ton, for bright annealing copper wire. It was first demonstrated in an experimental way that coal was the most expensive fuel for this particular operation, although it contained perhaps four times more B.t.u.'s per unit of cost than found in the gas. It further demonstrated the fact that the thermal efficiency of the gas furnace was several times greater than the coal furnace.

A large oil-producing and refining company used large quantities of manufactured gas for heating solder baths at their refinery, where there was almost an unlimited quantity of crude oil, fuel oil, gasolene and kerosene.

The industrial heating department of a large and well known gas company found from actual operations that under the best conditions of oil utilization they could substitute 1,000 cubic feet of a 600 B.t.u. manufactured gas for 5½ gallons of 142,000 B.t.u. oil. Where oil was used at a low efficiency this company found that 1,000 cubic feet of 600 B.t.u. manufactured gas could be substituted for 14 gallons of oil of 142,000 B.t.u.'s per gallon.

In other situations the same company was able to substitute 126 B.t.u.'s of manufactured coal gas for 210 B.t.u.'s of producer gas. Again, 253 B.t.u.'s of manufactured coal gas gave the same results as 504 B.t.u.'s of producer gas.

### Correct Basis of Comparison

The above occurrences confirm the statement that fuels cannot be compared in relative heating value by their B.t.u. content in the fuel state. The only correct basis of comparison is the heating value of the combustible mixture. This fact is well established theoretically. A few calculations will show that a coke oven gas of 600 B.t.u.'s per cubic feet will give a theoretical flame tem-

perature of 3550° F. and a heat content of 100 B.t.u.'s per cubic feet in the products of combustion, while a blue water gas of 300 B.t.u.'s per cubic feet will develop a flame temperature of approximately 4000° F. and a heat content of 107.5 B.t.u.'s per cubic feet in the products of combustion.

Yet in the face of these facts, both theoretical and practical, we find many practical steel treaters in favor of coal and oil because of their erroneous belief that the B.t.u. value of the fuel as fired to be the real measure of its utility.

The principal combustibles in the fuels under consideration are carbon, hydrogen, and their many combinations known as hydrocarbons, also carbon monoxide. In addition to these are the incombustible such as nitrogen, oxygen, sulphur, carbon dioxide and ash. The combustible elements when mixed with air give a flue gas composed of carbon dioxide, water vapor, sulphur dioxide, nitrogen and carbon monoxide. Furthermore, by changing the proportion of air in the flue gases gives rise to three general conditions within the furnace: a reducing, neutral, or oxidizing atmosphere. These conditions are essential and are of great importance in different heat-treating processes. They also have a very vital relation to fuel economy and furnace efficiency.

A reducing atmosphere (one in which an insufficient amount of oxygen has been admitted with the fuel to give complete combustion) is a condition often desirable in heating tool steel and other steel parts, in order that no oxidization or scaling action shall take place. The flue gases should show a small percentage of unburned gases.

A neutral atmosphere is one which is hard to obtain with any of the fuels except gas. It represents a condition in which just enough oxygen has been admitted to completely burn the carbon hydrogen and other combustibles present. In this case a flue gas analysis will show no free oxygen or unburned gases.

The condition most frequently found in furnaces is the oxidizing atmosphere, where an excess of oxygen is necessary to accomplish certain results, or where too much has been admitted through poorly designed apparatus. This condition is very noticeable in coal-fired furnaces, where it is necessary to burn the coal with a large amount of excess air. Such a condition within the furnace is harmful in many ways. It causes over ventilation and thus carries away much of the sensible heat of the unburned gases. It produces a chilling of the flame, lowers the temperature of the furnace, and thus reduces its thermal efficiency. Steel exposed to this furnace condition oxidizes very rapidly.

For industrial heating operations, gaseous fuel should always be mixed with air before the gas has reached the zone of combustion, and in the proper proportion to give the desired furnace atmosphere. For all metal-treating work, some mechanical means should be used to produce air at sufficient pressure and thoroughly mix it with the gas. This is of great importance in burning gas. Many devices are used, but all may be grouped under three general types.

### OTHER POINTS OF INTEREST

Fuel oil often contains a small percentage of water which lowers its heating value. For each one per cent. of water, the heating value is reduced 13.14 B.T.U's.

Fuel oil is particularly adaptable to heavy forging work such as drop forgings, heating of heavy bars, and so on.

Gaseous fuel is economical because it can be applied in a way most adaptable to the requirements of the piece to be heat treated.

(1) The Air Injector—air under a pressure of a few ounces to one or two pounds per square inch is passed through an injector. Gas is admitted to a chamber surrounding the injector and the high velocity of the air in passing through the injector opening entrains the gas and the mixture is then led to the burner. This method requires both air and gas piping to the injector. It further requires valves on both the air and gas pipes and these are changed by the furnace attendant to give the desired mixture.

(2) Gas under relatively high pressure—under a pressure of from 8 to 10 pounds per square inch gas passes through a small orifice and entrains air under atmospheric pressure. The resulting mixture is led to the burner located nearby.

(3) Gas and air-mixing machines—a machine designed for this special purpose is located at a convenient point. Air and gas are brought together inside the machine in any predetermined proportion within the limits required for combustion. By means of a pump or fan the mixture is distributed from this point by means of a one-pipe system to the point of consumption.

It is to be regretted that in the majority of gas-fired furnaces the air injector is used for mixing. This is largely due to a lack of initiative in the past on the part of gas engineers, and also on account of the ease with which an injector may be constructed. We have no particular antagonism to the air injector as a mechanical means of mixing the air and gas, but the greatest evil lies in the very uncertain proportions of air and gas thus obtained by means of manual adjustment of the valves usually administered by unskilled furnace attendants. It is no exaggeration to say that the ordinary furnace fitted with an air injector and a two-pipe system and operated by the average furnace attendant will use as much as 50 per cent. excess air.

With the high pressure gas aspirators and air-gas mixing machines it is very easy to make adjustments that will mechanically control the air-gas ratio to give the desired furnace condition. After this adjustment has been made it is only necessary for the furnace attendant to regulate one valve in order to give more or less heat as the occasion may require.

#### Transferring of Heat

The application of heat in furnaces to the metal to be treated is another subject of great importance and one too often overlooked. Heat may be transferred from one body to another, or applied to a body from the point of combustion in three different ways—by conduction, convection and radiation.

Heat transfer by conduction takes place when it is transmitted from one part of a body to another without the occurrence of motion in any definite part or parts of the body, intermediate points being heated meanwhile. Thus a steam radiator becomes hot on the outside due to conduction of the heat of the enclosed steam within the radiator which passes through the iron to the exterior. Placing one's bare foot on a tile floor in a room well heated will give the impression that the tile is very cold. While if the foot is placed on a rug it will feel much warmer. As a matter of fact the tile and rug are perhaps of the same temperature, but the tile being a much better conductor than the rug, absorbs the bodily heat from the foot much quicker than the rug and is therefore known as a good conductor.

Heat transfer by convection takes place when it is conveyed from one place to another by the movement of air currents, or the circulation of liquids. When heat is applied to the bottom of a pan of water, almost instantly minute vapor bubbles form in the bottom of the vessel. These presently ascend and impart heat to other parts of the water, while cooler water takes its place at the bottom.

Heat transfer by radiation takes place when heat is transferred from a hot body to a colder one by a wave-like motion of the ether that occupies all space. The ordinary cast iron steam or hot water radiator starts a wave-like motion of the surrounding ether in all directions, and as these travel outward from the radiator similar to the waves of water when a stone is thrown into a still pond, the heat is imparted to the room, and this transfer of heat is called radiation.

For all practical purposes of furnace design the heat of combustion is transferred to the material to be heated by means of convection and radiation. Heat transfer by conduction is to be avoided as much as possible, for by this means the efficiency of the furnace is very much lowered if heat is allowed to be

conducted through the furnace walls and lost. For this reason it is important that all furnaces should be thoroughly insulated with the best kind of non-conducting material in order to reduce such losses to a minimum.

In the usual type of furnace, the heat is transferred by convection to the walls and arched roof, and from these a radiant heat transferred to the material to be heated. Then in order to get the maximum amount of radiant heat from the gas burned, there must be as near complete combustion as possible with a minimum amount of flue products.

The proper furnace conditions are hard to obtain with any degree of certainty or uniformity when coal, coke or oil are used to produce the heat. On the other hand, gas, on account of its flexibility of application, can be made to accomplish far better results.

Coal and coke are seldom considered to-day in connection with the larger and more important heat-treating operations because of the difficulty in maintaining proper furnace conditions.

Oil can no longer be considered a cheap fuel for furnace heating on account of the economic demand for it for other purposes.

Natural gas supply is continually growing less, as evidenced by the increase in shortage during the winter and the construction of manufacturing gas plants to augment the supply.

Producer gas plants and others that use coal at the sacrifice of the valuable by-products will sooner or later go into the discard.

It is possible we are approaching the dawn of a new day in industrial economy, a day when the gas manufacturing company will become a central fuel station from which can be supplied the entire fuel demand for industrial heating, but on account of the ridiculously unreasonable standards of candle power and heating value placed upon the gas companies by the State Utility Commissions in the past, it has not been possible to produce a gaseous fuel of the greatest economic advantage.

### Question of Proper Fuel

The question of fuel costs is a very vital one to every manufacturer. Unfortunately a decision has often been reached on a purely heat unit basis, without considering the efficiency of application and many items of expense incurred in handling such fuels before they reach the zone of combustion.

In the foregoing remarks the aim has been to state a few of the characteristics of each fuel together with some of their advantages and disadvantages. It must be remembered that the true fuel cost is not the cost of coal per ton, oil per gallon, or gas per thousand cubic feet delivered at the factory, but rather the cost of these fuels delivered to the hearth or burner of the furnaces.

There are many items of expense such as the handling of coal, removal of ashes, investment in storage equipment, labor, time lost in getting started with coal or oil, the noise and smoke nuisance so peculiar to the oil fire, and the deteriorating effect of coal and oil on the furnace causing frequent repairs. The proper fuel is the one which, regardless of cost per ton, gallon or cubic foot, gives the corerct heat application, perfect combustion, and proper temperature control.

Therefore in the final analysis the true furnace efficiency is measured by the quality of the work it produces and the cost per unit of product, and not upon the relative cost per unit of fuel consumed.

## CAPACITY OF LOCOMOTIVES

(Continued from Page 40)

with deep fireboxes between frames have become obsolete on many large roads, but on the small roads and on branch-line and local train service in much of the New England territory these engines, modernized as far as consistent, should be carefully considered where the traffic conditions warrant.

Because of limiting weight conditions, Mogul or 2-6-0 type locomotives have been assigned to passenger-train service on some outlying divisions. The application of superheater and piston-valve steam chests with outside steam-pipe connections as the principal features of improvement has increased the economy of these engines, added one passenger car to their tonnage capacity, and reduced train delays. Outside valve gears were not applied, shop limitations preventing, but their addition is desirable.

Atlantic-type locomotives having outside valve gears have had their capacity and economy increased by the application of the superheater. This work permitted the use of the engine in long-distance through service which was not previously successful.

Consolidation locomotives reconstructed with superheaters, new piston-valve cylinders, outside valve gears, new front-frame sections, and frame cross-ties have also had their capacity increased, and have been successfully used in regular freight service on a mountain division needing much power. The cost of the above-mentioned improvements, including heavy general repairs and entirely new fire-boxes, would not exceed one-half the cost of new locomotives of the same capacity.

When rebuilding locomotives there is a favorable opportunity for replacing old tenders as well, transferring the latter to older locomotives for spare use or as substitutes for damaged equipment. When the condition of old steel tender frames requires that they be replaced, the one-piece steel casting and a larger-capacity tank should be used, as both will reduce future expense in repairs. The success of autogenous welding eliminates any objections to the use of large steel castings for fear of breakages.

Tanks should be reconstructed in coal space to permit gravity delivery of the greatest amount of fuel that is possible at the coal gates within reach of the fireman's shovel. Application of power-operated coal pushers should be made to tanks where alterations for the gravity delivery of coal cannot be satisfactorily made and where the service conditions will show a saving in expense by its use over hand methods of shovelling forward coal while on the road or at short lay-over stations. Moving forward the rear coal board or plate on tanks and building higher side plates or "dickies" is one method which has been successful in making the maximum amount of coal accessible at the gates. Furthermore, care must be taken not to overload the journals of the forward truck axles.

---

By means of a method of chemical analysis, in which the electric arc is utilised, Mr. W. R. Mott, an American research chemist, claims to identify readily about sixty-five elements, picking them out from their ores, compounds with oxygens, or alloys. According to the Chemical Trades Journal, the apparatus required is simpler than that for spectroscopic analysis, and includes a carbon arc lamp so enclosed as to project upon a screen an image magnified 20 diameters. A half-gram sample of the material to be tested is placed in a cup-like cavity, two-fifths of an inch wide and deep, hollowed out of the positive lower carbon of the pair. The elements are recognized by various phenomena, including the nature and colors of the material deposited on the carbon pole from distillation, the smoke, sparks and flame-tip color shown, and the odor of the fumes emitted, with many other peculiar characteristics. The smoke emitted from the hot upper carbon when the arc is broken appears only when molybdenum is present, being a delicate test for that element. The present of calcium is shown by its peculiar red color, and characteristic odors reveal iodine, arsenic, and tungsten. Many elements difficult to determine in other ways are said to be clearly identified by this new system.

## CATALOGUE ON CRANES

The Milwaukee Electric Crane and Manufacturing Company of Milwaukee, Wisconsin, has just issued a new 48-page catalogue illustrative and descriptive of their complete line of cranes. Much valuable information, the result of twenty-five years of active experience in the designing and building of hoisting machinery for shops, foundries, steel plants, and other establishments, is incorporated in this book.

Those interested in electric cranes or hoists, and especially in the prevention of accidents, will find this book chuck full of interesting data. A section of the catalogue is devoted to the horizontal drilling and boring machine made by this company and which is especially suited for operating, at one setting, on pieces too long or bulky for the usual type of machine.

# Have You Tried This Contest Yet? If not--- Do so Now

Do you want to win one of these scales?

It's very easy, and at the same time you add to your store of knowledge. The details are given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

## What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

There were 8 correct answers to our Dec. 16th contest. The ninth answer was so well recorded that we cannot help but send a scale to him as well as the winner. Here is how it happened: GORDON B. RILEY, who is the chap who had all correct but one, was really the fellow who would have been correct had the advertisement appeared for which query No. 11 was intended. We expected to run an advertisement for the W. S. Rockwell Co. In that advertisement was a cut of a blast gate. The reading matter suited our query No. 11 exactly. The advertisement was left out, however, too late for our changing the query. Mr. Riley stated in his letter that the advertisement that seemed to him as best suited to the query had appeared on Page 53 of our Dec. 9th issue. As this was perfectly correct, we award him a scale as well as the winner.
Here is the actual winner. R. P. BROWN, of the Garlock Walker Machinery, Ltd., Toronto, Canada. He stated Kearney & Trecker was the answer to query 11. This tallied correctly with the advertisement that appeared. Five others were correct in their lists, but were several days behind Mr. Brown in sending their replies. The others who were correct are as follows:
W. O. Bird, Edmonton, Alta.; Frederick Cubaynes, Chicoutimi West, Quebec; E. Bowers, Welland, Ont.; G. A. Todd, Penetanguishene, Ont.; J. J. Doyle, Brantford, Ont.; Geo Land, Peterboro, Ont., and K. M. Horton, Yarmouth, N.S

**CONTEST FOR JAN. 13TH ISSUE**

**Contestants are required to write us, stating to which advertisements we refer in this number.**

1—Something said to be a service to Canadian industry.
2—How to obtain full details of every heat treating operation.
3—How to keep down the cost of upkeep.
4—What to do if you desire strength and dependability.
5—How to get high speed combined with safety and power.
6—How to obtain air and steam tight jobs.
7—Something to watch for carefully.
8—How to secure something original.
9—How to obtain versatility.
10—How to create confidence.
11—A product that can be adopted for motor or chain drive if desired.
12—How to find what you want.

**These are Correct Answers for List from Dec. 16 Issue:**

1—A. R. Williams Co.
2—Wisconsin Electric Co., Ltd.
3—J. T. Ryerson Co.
4—J. Morrow Screw & Nut Co.
5—Union Carbide Co.
6—Canadian Blower & Forge Co.
7—General Combustion Co.
8—The Frost Mfg. Co.
9—The Shore Instrument Co.
10—The Independent Pneumatic Tool Co.
11—Kearney & Trecker Co.
12—Butterfield & Co.

## Closing Date for This Contest is February 3rd!

# WELDING AND CUTTING

# Foreign Comment on Effects of Alloys in Steels

## A Discussion of Welding in General—English and French Journals Comment on a Previous Statement Made in One of Our Welding Lessons—They Prove Interesting

By W. B. PERDUE, Director Welding Department, Healds Engineering School, San Francisco, Cal.

AN article which was originally printed in the June 3rd issue of Canadian Machinery seems to have attracted considerable comment, both favorable and unfavorable.

Despite the fact that the article contained the statement that "American products are made which excel by far any imported article which can be procured," it was translated into other languages and printed in its entirety by several foreign metal trades journals.

In this article, as in other writings on the subject of welding, I gave out the results of exhaustive tests which can be duplicated wherever tensile machines and other apparatus are available. The tests made by myself have been repeated in many other sections of the country, and in each test the results have been identical. As the engineer of a large steel producing concern engaged in the manufacture of special welding rods put it:

"We enclose a table of tensile tests applied to parts welded in various parts of the country by operatives both skilled and unskilled. You will note that these are in full accord with your articles on the subject. We label all our products with our own trade names, omitting any statement which would indicate the fact that they are steel or iron. Some welders use our steel wires thinking them to be wrought iron, and would even quit buying if they were disillusioned. The adverse comment abroad on your article merely shows the fear of American competition—in fact we have good cause to believe that these criticisms of your article have brought inquiries which may lead to considerable export business."

It is so easy to make an actual test to determine the merit of a welding material that it seems unusual for the editor of a reputable trade journal to express an opinion unsupported by facts. The following extract from a letter written by one of the best known engineers seems to bear out this statement with regard to the London "Acetylene and Welding Journal."

"The printing in our local 'Acetylene and Welding Journal' of a criticism of your article on the 'Effects of Alloys in Steels' is most unfortunate. The tone of the criticism is such as to foster and perpetuate the old idea that wrought iron can be used as an all purpose filling material."

"We entirely agree with you in your statement that 'the metal added must be similar in analysis to the original metal.' It is impossible to procure iron with sufficient tensile strength for use in life and death welds."

### From a Well Known Paris Authority

"Where welds are to be made in alloy steels we consider it of essential importance that the nature of the alloy be determined, and a steel filler rod selected that will supply the ingredients most liable to be destroyed or burned out in the execution of the weld."

### From a Large English Firm

"Recent tests of American welding rods, made since the appearance of the criticism of your article, were very much of a surprise to us. Tests of American products bought in open market several years ago proved them far inferior to those now available. We do not regard them quite the equal of our —— fillers, but believe those tested to be far superior to the average product of our competitors." Naturally, the salesman can not afford to admit that anything is superior to the goods he is selling.

Evidently the printing of the criticisms of these articles has served to attract attention to the articles themselves and incidentally to the quality of American goods as now produced and sold.

I do not for a moment question the sincerity of those who expressed criticisms of the article in question. I do question, however, the policy of expressing an opinion without determining the facts. We know by reason of oft repeated experiments that the tensile weakness of the very best wrought iron is such that it can not serve to bond parts of alloy steels which may have a tensile strength more than double that of the iron filler. To give the impression that it is unnecessary to make a special study of alloy steels and in each case select the proper filler is to promote a dangerous doctrine.

The phenomenal growth of the automotive industry in the United States, which eclipses that of all other countries combined, and of many other industries in which similar uses of the oxy-acetylene process is slowly but surely superseding more costly means of metal joining has afforded a wonderful incen-

A PECULIAR JOB FOR THE WELDER.

tive to scientific investigation in this country.

Vague theories, which may still be common in countries where welding is considered only as a means for emergency repairs, have been dissipated. When a demand is found to exist those who are in position to increase the markets for their products by producing a satisfactory article are quick to realize its possibilities and to supply the need. Think, for instance, how valuable would be a ferrous metal which could be used to produce a true weld in malleable iron parts!

In other countries the interest in welding is just as keen as in ours. The opportunities for invention, however, are lessened, due to the fact that there are not enough competing concerns able to finance and carry on the expensive experiments necessary to determine the value of some new idea. Fortunate indeed is the student of welding who lives in North America.

### Steel—the Master Metal

The amount of iron produced as wrought iron to-day is less than 10 per cent. of the amount produced 20 years ago. The demand for this particular product is rapidly waning. On the other hand, the demand for steel—and especially for high-grade alloy steels—is increasing with greater rapidity than that of any other known industrial metal.

Some day these various alloys of steel will be standardized and classified. The International Acetylene Association is now calling for facts stating the chemical analysis of the steel plate used in the construction of pressure containers and the analysis of the filler found to give the best results therewith. Such information will some day be available. The writer holds that the welding and steel industries are both too young for the tabulation of complete information on this subject, although much may be accomplished in the very near future. The principles given in my article in the May issue and repeated below are intended to govern the choice of fillers until such information is complete.

"First, that the steel rod added must be similar in its analysis to that of the original metal."

"Second, that none of the essential characteristics of the original metal shall be destroyed in the execution of the weld." When there is a tendency to lessen the proportions of any of the component alloys, a welding rod which will make good this loss must be used.

"Third, that the grain of the weld shall be equally fine as the original section welded." Heat treatment or other means necessary to produce this result may be used where a 100 per cent. weld is sought.

My own experience in supervising an average of more than 1,000 welds per month has taught me that etching, microscopic and tensile tests are essentials of the business, and that any appreciable change in the analysis of the plate used in pressure containers or other work where the strength of the weld must be from 80 to 95 per cent. that of the rolled plate demands a specially selected filler —a filler with a tensile strength far in excess of the best wrought iron that can be manufactured.

Any weld made by a good workman that is "beaded through," that is, in which the ripple shows on the reverse side, and that is very slightly reinforced will stand a greater tensile pull than the plate itself—provided the right kind of filler has been used, together with a torch which stirs the gases into thorough mixture.

In this series of articles I have outlined the method of preparation of almost every type of weld in steel; have emphasized the necessity for securing proper penetration; and have shown the beginners how to practice torch movements until they attain proficiency.

### POINTS BROUGHT OUT

That sometimes a product is labeled incorrectly. In one case welders used steel wires, thinking them wrought iron.

Recent test of American welding rods proves them to be of the best quality.

The amount of iron produced as wrought iron is less than 10 per cent. of the amount produced 20 years ago.

Every welder should have a few samples of his various alloy steels tested, then label them, so that he can determine the characteristics of the sparks. In a short time he will be able to distinguish the common alloys by sight without grinding.

Others have pounded the truth home through these columns in regard to these matters, but we've had many failures. Why?

Because many of our welders do not know the analysis of the metals upon which they are working nor the filler that they are using. More than 75 per cent. of the welding supply houses can not tell you the analysis of the rod they "personally guarantee." Try it. Next time you meet your supply man ask him the analysis of the various rods he sells.

Now I do not mean that every welder must install a chemical laboratory in his shop, but he should at least obtain a few samples of the various alloy steels and have them properly labeled to use as wheel tests to determine the characteristics of the spark. In a few weeks he will be able to distinguish most of the common alloys by sight without grinding.

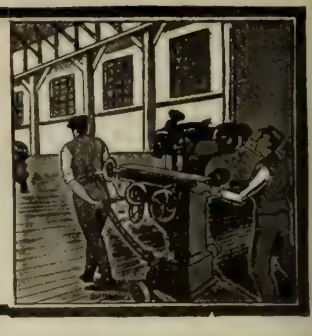
It took years to develop the cast iron welding rod with an increased amount of silicon and the bronze welding rod with the correct proportion of phosphorus and aluminum. Even now many shops are trying to get by with common "Tobin" or "manganese," instead of a specially prepared and drawn welding bronze.

My experience has been that best results have been obtained with steel plate and rod in which the percentage of phosphorus and sulphur are kept at a minimum. The percentage of other alloys, including carbon, should be as nearly equal as possible. I can furnish the names of dozens of operators who can make welds with "similar metal" that will stand greater strain than the balance of the plate.

### Reinforced Welds

Lastly, a word to the critic. The welding industry needs facts. If you have obtained extraordinary results with a filler in which the amount of carbon was so many per cent. less or more than the plate welded, and a certain increase or decrease in the amount of manganese or other alloys was found beneficial tell us about it either through these columns or by personal letter.

Possibly, too, we owe our brothers across the water some sort of an apology. In making the statement "American products are made which by far excel any imported article which can be procured," we referred to the markets of North and South America. We did not hope to see our original article quoted all over Europe. Surely with the same formula, materials and facilities as are used in the production of the highest grade American products they could be duplicated in any other part of the world.



## THE WEIGHT OF A BLOW

Should there be a relation between the size of a tool and the weight of the blow struck? Certainly! For would not the use of a 7 or 10-lb. hammer, on a ¼ punch or chisel soon ruin the tool? It may be shown as a ready example of this that while you can drive a 16-gauge 2 in. wire nail into an ordinary brick until its head is flush, if you use a 4 oz. to 6 oz. hammer, yet if you use a 2 lb. hammer the nail will not enter, but simply collapse; in effect this is the same with all percussion tools. If you have a big-bodied chisel or punch you can use a sledge hammer on it, but if you have a small-bodied tool only a small hammer can be effectively used, and for the usual ⅛ in. to ⅝ in. hexagon steel punches and chisels more work can be done with a ¾ lb. to 1 lb. hammer than with one of larger size, owing to more of the force being utilized.

Five men were seriously burned about the face and arms, when one of the employees of the Pratt and Letchworth Co., Brantford, stepped back suddenly, striking a man carrying a ladle of molten metal.

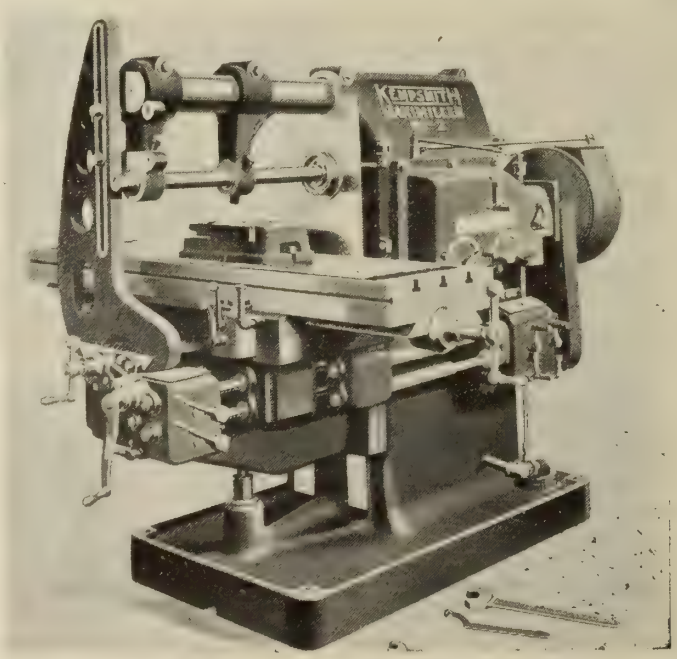
# DEVELOPMENTS IN SHOP EQUIPMENT

## NO. 2 MAXIMILLER

The Kempsmith Manufacturing Co., Milwaukee, have placed on the market their No. 2 plain maximiller. This machine is of similar design to their No. 4 size and has the same balanced weight, rigidity, convenience of operation and efficiency in production. Its size adapts it to the medium heavy classes of automobile and aeroplane work, and it will also be found valuable in tractor, steam turbine and agricultural machinery plants. The very highest class of materials obtainable are used. All gearing stock is purchased to exact chemical analysis and is scientifically treated for the particular use to which it is put. Much of the shafting, especially that in the speed train, is also heat treated alley steel.

The column, knee, saddle and table, which constitute the main frame numbers, are of semi-steel, and have been carefully designed in regard to relative weight and strength. An exceptionally large area of base provides stability for the entire machine. No weight whatever has been added merely to have a heavy machine. Every pound of metal used is well placed, and serves a useful purpose.

The knee is of the solid top design, there being no openings whatever in the top plate of the knee. This construction serves to better resist clamping strains and the torsional effect of the table overhang. The side walls of the knee are practically solid, there being but two small openings, which are closed by plates. Cross-feed screw is located in a shallow depression in the top of the knee midway between the saddle V's. The greatest possible strength and accuracy is the result as the pull or thrust of the cross-feed screw is applied to the centre of the saddle.



Column is well ribbed internally and has very few and small openings. The reservoir for the speed drive oil forms a solid rib or cross member midway of the column height, which has a great stiffening effect on the column. Saddle is long, heavy and rigid. Drive to table is located near end of saddle, which leaves the center solid where the most strain comes. Table is 12 inches wide with 56 inches working surface in length. Table gib is of adjustable taper type with locked adjustment.

The overarm is a solid steel bar 4¼ inches diameter and is a patented "wedge lock" type which keeps the arbor in alignment with the spindle at all times. The spindle hose is of patented type which provides for driving face milling cutters in either direction and also permits cutters to be quickly and easily removed. Right hand design has been used which means that normal direction of spindle rotation is correct for standard drills and boring tools. A spindle reverse has been incorporated in the machine for the reason that in order to get cutting strains in proper direction on gibs and tables a face mill must be run in the opposite direction to a spiral or slab mill.

The clutch is of friction plate type operated by a hand lever located at the front of the machine where it can be easily reached by the operator. Friction surfaces of clutch are large in diameter and are forced together by a combination toggle and plain lever movement which gives the required pressure on the plates with very little effort on the operating handle. Clutch is adjustable for wear without dismantling the unit. A brake operating on the reverse throw of the clutch lever overcomes the momentum of the spindle gear train and stops the spindle quickly.

The drive pulley is 15 inches diameter, takes 3½ inch double belt and runs at 400 R.P.M. It is mounted on ball bearings and with the clutch is enclosed in a protecting housing. The control of the longitudinal movement is by two levers, one for the feed and one for the power quick traverse. The operator merely pushes the one required in the direction he wishes the table to move. The knee and saddle movements are both controlled by a second set of levers, the unit which shall move being determined by push pins located in close proximity to the respective hand feed handles; while feed or quick traverse is determined by which lever is pushed. Operator can control the movement of the table in any direction either by power feed or quick traverse without moving from his position at the front of the knee.

The cooling system is a part of the machine. Pump is of the centrifugal type driven through a clutch which can be disengaged if the nature of the work does not require the use of a cooling fluid. The capacity of the pump is about 15 gallons per minute delivered to the cutter. Lubrication of all working parts has been given careful consideration in the design of the Maximiller. The gears and bearings in the entire speed and feed mechanism run constantly in oil and are lubricated by splash. The only exceptions to this are the sight feed oilers

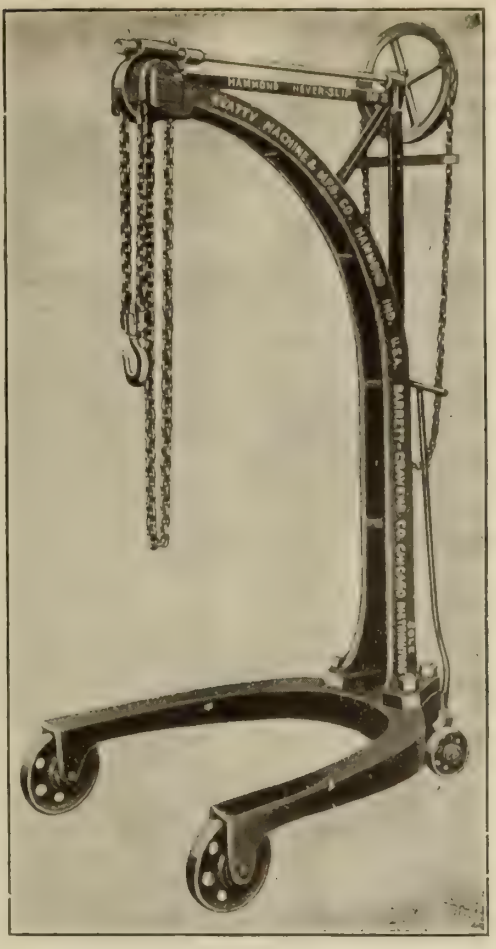
GENERAL VIEW OF THE NO. 2 MAXIMILLER

sed to supply fresh clean oil to the pindle bearings and drive pulley. The ubrication of all mechanism supported y the knee is centralized at two points hich make it certain that none will be verlooked.

The spindle is very large and runs in hosphor bronze bearings which are asily adjustable to compensate for wear. ll other shafts in the speed transmission run on ball bearings. The entire pindle drive is located in an oil tight ase and runs in oil. Feed change echanism provides 18 changes of feed anging from 5-8 inch to 25 inches per inute in geometrical progression. The ars are all heat treated steel and run n an oil bath.

### Quick Traverse

The power quick traverse is available r all table movements without disturbg the set up for whatever rate of feed ay be in use. The available feed rates main constant, but power quick traerse rate has been reduced for the cross d vertical feeds to compensate for the ort travel distance of the former and e greater load in the latter case. The ngitudinal power quick traverse, is at e rate of 100 inches per minute while e cross and vertical travel is at e rate of 36 inches per minute. Oiling rections for this machine are simple d complete, a small plate on the speed being all that is necessary to explain em to new or unskilled operators.



The drive is of the single pulley type rough a train of gears giving 18 anges of spindle speed ranging from 16 400 R. P. M. All speed changes are ared by sliding gears, there being no ubler gears, clutches or locking pins. ere are never more than three pair of ars in mesh. All heavy cuts are ven through the large spindle gears, t gear arrangement being such that cutters above 3 inches diameter are mally driven through this gear. hen desired and at an extra cost we furnish the above machine arranged f motor drive through belt in which e the motor recommended is 7½ H.P., ning at 1,200 R. P. M.

## PORTABLE CRANE

he Barrett-Cravens Co., Chicago, Ill., ve placed on the market a portable ne which is claimed to have various standing features.

he crane is of all steel construction, al the load is locked at all points of vel. The lifting mechanism is of the rm and gear type, thus allowing the ad to be raised to any desired height, en to a fraction of an inch. This is, ofcourse, a desirable feature when assembling or dismantling heavy machiner

he hoisting worm gear is made of bronze, and the screw is cut from solid steel shafting of goodly proportions.

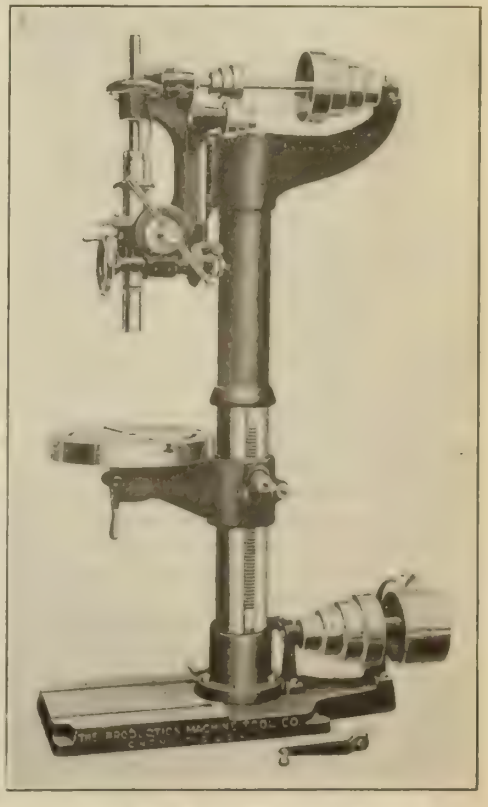
GENERAL VIEW OF THE PORTABLE CRANE.

Both are enclosed in an oil tight cast housing to permit proper lubrication. The axle is chrome nickel steel, heat treated, and Hyatt roller bearings are used in all the wheels. The treads of the wheels are chilled to ensure long wear. The Ontario representative for this concern is the Anglo-Canadian Metals, Ltd., 52 Spadina Ave., Toronto, while B. and S. H. Thompson & Co., Ltd, 210 McGill St., Montreal, handle the other provinces in Canada.

## DRILL ATTACHMENT FOR MILLERS

The Purves Manufacturing Company of Syracuse, N. Y., are placing on the market a special attachment for the drilling of holes in work carried on the table of the milling machine. The fixture is so designed that the work may be located on the table without the use of a jig and the holes drilled to any desired angle by swinging the attachment to the required position. A small hand lever is provided for feeding the drill, this method giving a more sensitive control and aiding materially in preventing drill breakage. The feed lever may be placed in different positions to accommodate various shapes of work. For depth drilling adjustable stops are provided.

## 22-INCH UPRIGHT DRILL



The Production Machine Tool Co., Cincinnati, Ohio, have placed on the market a new 22-inch upright drill. This machine has stationary head, bronze bushed throughout. It is built to do the regular type of drilling, boring, tapping, and facing work up to its range of 1¼-inch diameter drill.

The machine is regularly built with power feed, but this can be omitted if desired, Back gears, and tapping attachment can be added together with the type of drive best suited to conditions under which machine has to be used.

The frame is of ample proportion. The column is of tubular section, and if sufficient stiffness to withstand all strains. The table arm is a single casting and of box construction. The table is well ribbed, and has four tee slots of the same size as those in the base. Four radius slots are also provided. All other parts are proportioned to withstand heavy usage.

The drive is by means of tight and loose pulley through driving cones of large diameter and wide face. The driving level gears have a peripheral speed of less than 800 feet per minute. The spindle sleeve is bronze brushed, and the spindle has a suitable ball bearing for thrust. Four spindle speeds are obtainable on the plain machine, with four additional speeds through back gears.

A by-law was passed by the ratepayers, Dunville, Ont., authorizing an expenditure of $40,000 on a four-room addition to the public school.

## The Cancellation Germ

ONE of the poorest things that has been allowed to grow up and become incorporated in our business system is the cancellation of contracts or orders.

There are undoubtedly cases where the only way out is to cancel, but the tendency of our commerce and trade should be set against this practice rather than in favor of its continuance.

Just this week Canadian Machinery talked with British agents in Canada, who were certain they could not take the business of certain Canadian firms to their houses again because it would not be considered until such time as they had discharged the obligations now on their books, but which they had seen fit to cancel.

In most cases the first intimation given that there was any intention of cancelling was when the expressman brought the goods to the door of the company's plant. Then the only word was to the driver of the wagon, and it ran like this, "Take these back, we don't want them."

There were cases in which these orders had been placed some months ago. The agent here had taken the business and sent it to his home office, where it had gone through the usual work in the factory and in some instances special work was required to meet the requirements of the firm ordering the goods.

There are too many contracts cancelled in this country.

A contract is a business obligation and if the firm to whom it is given lives up to its terms, it is the legal and moral duty of the purchaser to live up to his part and accept the shipment.

The reason why these business obligations are not discharged is, in the majority of cases, because it will not pay to do so.

It pays better to disregard business obligations, therefore disregard them and let the other firm worry about what is to be done about it.

Canada needs more common, every-day honesty in dealing with such matters as disregarded business obligations. It is a vicious practice and once started, strikes farther than any one would dare do in any other way.

Going through a season such as we are now, with contracts being cancelled simply because it does not pay consignees to honor their orders, creates a feeling of business instability that is hard to overcome and difficult to counteract.

It is generally understood that where a firm fails to make shipment on time, or where the goods are not up to samples, or faulty in any way, there are grounds for refusal and rejection. It is right and proper that such should be the case. This is a perfectly legitimate practice, and a defence for good business methods.

But this is far removed from the cancellation craze that has taken business by the throat in this country.

The way to weed out the cancellation germ is to weed it out.

Let us have in Canada a business community that will recognize contracts, and regard them as business obligations which they are morally bound to discharge.

## Time To Face Facts

THE International Harvester Co., at their Hamilton plant, publish a paper called "The Bulletin" each month. The current issue contains an appeal to the employees from the management. It goes on to point out that conditions are changing and that it is a harder matter for the firm to keep going than it was a few months ago.

Many a plant will find its own case stated in the appeal that is made for the elimination of the scrap heap.

Here is the way in which the case is stated, after reviewing the money markets, and showing how much more it costs to borrow necessary money now than formerly:

"So you see where we stand. There is no way to dodge the issue. We have got to meet it and go through. Every man and woman on the payroll will have to get down to business. Every one of us will have to save money for the company. We will have to get practical and ask ourselves practical questions:

"How much does a scrap pile cost?

"What does one bolt, lost or scrapped, cost, when multiplied by a thousand or ten thousand?

"What does a pound of brass cost, or a handful of nails, or three sheets of paper, or a pocketful of pencils—multiplied by the number of employees and purchased with borrowed money?

"How much does fifteen minutes of wasted time cost the company?

"What is the penalty of an hour a day lost from creative work?

"How much does it cost for every call a salesman does not make during the day, and for every unproductive call he does make?

"The time has come to ask ourselves the bluntest and most practical questions and get our schedules down to bedrock. In other words, we had just as well face it—to be an asset to the company we will have to be efficient.

"And it is an exceedingly poor time for any man to be anything but an asset to his company."

---

It is stated in a recent report for 1919 that the total amount of tar distilled in the United Kingdom equalled 1,509,043 tons, of which 1,402,987 tons were obtained from gas and coke oven works. For pitch, out of a total of 698,290 tons, the gas and coke oven works contributed 636,435 tons.

# Canada's 1919 Iron, Steel and Tool Trade

DURING the year 1919 Canada imported from other countries a total of $181,332,310 in iron and steel. The year before it amounted to $173,340,779. The year 1920 may show a decrease. The great bulk of this came from United States.

Canada imported more iron and steel in 1913 than in 1917.

Here are some of the amounts coming in during the year 1919:

| | Tons | Value |
|---|---|---|
| Pig iron and kentledge | 35,800 | $ 1,022,871 |
| Ferro-alloys and chrome | 16,423 | 943,584 |
| Ingots, blooms, billets | 12,135 | 494,101 |
| Scrap iron and steel | 39,790 | 482,963 |
| Plates and sheets | 183,061 | 12,820,340 |
| Tin plate and sheets | 43,407 | 6,436,047 |
| Bars, rods, hoops, etc. | 147,726 | 12,771,836 |
| Structurals | 184,813 | 11,142,997 |
| Rails and connections | 14,059 | 774,985 |
| Pipes and fittings | 1,277 | 90,879 |
| Nails and spikes | 2,359 | 228,580 |
| Forgings, castings | 19,935 | 3,325,859 |
| Exports from Canada include: | | |
| Harvesters and binders | | $2,773,756 |
| Mowing machines | | 918,635 |
| Cultivators | | 638,741 |
| Ploughs and parts of | | 2,833,743 |
| Gasoline engines | | 1,184,664 |
| Locomotives and parts of | | 5,874,091 |
| Wire nails | | 1,302,413 |
| Other machinery and parts | | 5,852,327 |
| Bars and rods (52,191 tons) | | 3,394,894 |
| Rails (30,737 tons) | | 1,297,836 |
| Structural (5,515 tons) | | 465,989 |
| Imports in lines of iron, steel and machinery show: | | |
| Cream separators, steel bowls, and other parts | | $1,238,657 |
| Harvesters, self-binding | | 307,907 |
| Ploughs and parts of | | 1,794,736 |
| Threshing machines | | 822,819 |
| Plough plates, mould boards, or shares, land sides, cut to shape from rolled plates of steel, but not moulded, punched or made | | 417,711 |
| Automobile engines | | 5,586,127 |
| Gas and gasoline engines | | 1,751,824 |
| Gas and gasoline engines, n.o.p. | | 2,324,604 |
| Castings, malleable, n.o.p. | | 334,325 |
| Castings, iron, n.o.p., not malleable | | 1,037,744 |
| Adding machines | | 783,361 |
| Air compressors | | 225,622 |
| Electric motors | | 1,387,834 |
| Paper mill machines | | 1,004,990 |
| Rolling mill machines | | 582,422 |
| Other machinery of iron or steel, n.o.p. | | 16,353,427 |
| Power lathes | | 402,473 |
| Rolled iron or steel and cast steel in bars, bands, sheet or plate | | 4,298,705 |
| Bar iron or steel | | 2,274,770 |
| Iron or steel plates, coated with tin—"tin plate" | | 6,436,047 |
| Iron or steel plates, 30" wide, not less than ¼" thick, n.o.p. | | 1,618,099 |
| Iron or steel sheets, polished or not, No. 14 gauge and thinner, n.o.p. | | 2,831,411 |
| Skelp iron or steel, sheared or rolled in grooves, for making wrought iron or steel pipe | | 4,139,860 |
| Iron or steel angles, tees, beams, not punched | | 1,480,205 |
| Iron or steel angles, beams, channels, etc., not less than 35 pounds per lineal yard | | 3,405,724 |
| Iron or steel beams, sheets, plates, for ships or vessels | | 5,389,766 |
| Pig iron | | 1,022,871 |

**Iron Blast Furnaces in Canada, in 1919**

Dominion Iron & Steel Co., Sydney, C.B.: Six completed furnaces; one of 350 tons capacity and five of 250 tons capacity each per day; No. 1, operated 309 days; No. 2, 214 days; No. 4, 237 days, No. 7, 126 days; two furnaces idle throughout the year.

Nova Scotia Steel & Coal Co., Ltd., New Glasgow, N.S.: Two stacks and one set of stoves at Sydney Mines, C.B., of 250 tons capacity; stack No. 1, operated 156 days.

Londonderry Iron & Mining Co., Ltd., Londonderry, N.S. (in liquidation): One furnace of 100 tons capacity idle throughout the year; not operated since 1908.

Midland Iron & Steel Co., Ltd., Midland, Ont.; Acquired in 1918 the Midland blast furnace plant of Canada Iron Foundries, Ltd., of Montreal, Que. One furnace of 130 tons capacity at Midland, Ont., operated 215 days.

Parry Sound Iron Co., Ltd., Midland, Ont.: Acquired in 1918 the blast furnace plant at Parry Sound, Ont., formerly operated by Standard Iron Co., Ltd. One furnace 90 tons capacity rebuilt and operated 240 days.

Standard Iron Co., Ltd., Deseronto, Ont.: One furnace at Deseronto with a daily capacity of 60 tons, operated 160 days.

The Steel Company of Canada, Ltd., Hamilton, Ont.: Two furnaces, one of 260 tons capacity, operated for 341½ days, a second furnace of 430 tons capacity operated 285 days.

Algoma Steel Corporation, Ltd., Sault Ste. Marie, Ont.: Four furnaces at Steelton, near Sault Ste. Marie, two of 300 tons capacity each; one of 500 tons, and one of 400 tons. No. 1, in blast 285 days; No. 2, 364 days; No. 3, 171 days, and No. 4, 141 days.

The Atikokan Iron Co., Ltd., Port Arthur, Ont.: One furnace of 175 tons capacity idle throughout the year, not operated since 1911.

The Canadian Furnace Co., Ltd., Port Colborne, Ont.: One furnace of 325 tons capacity operated 363 days in 1919.

Canadian Steel Corporation, Ojibway, Ont.: Two stacks under construction, at the end of 1919 foundation had been completed for two blast furnaces of 550 tons each.

---

"Railroad and Locomotive Engineering":—This isn't much of a railroad story, but it is mechanical enough to pass muster, and it is aptly illustrative of some parallel things that were done during the joy-inspiring period of government control. Things were pressing in France and the ordnance department in a certain city were ordered to gather together all pulleys possible and ship them forthwith. As no ordinary pulleys were obtainable a telegram was sent to Washington that they could not get any ordinary pulleys but they could get a quantity of split pulleys. Whereupon a prompt reply was sent from the supreme ones at Washington: "Ship the split pulleys, if they are not too badly split." There seems to be no place in the world so sure to harbor incompetents as some of the upper reaches of government appointive service.

# MARKET DEVELOPMENTS

## Prices Firm in Steel and Machine Tools

### Makers Claim There is No Advantage in Quoting a Lower Price as Buyers Are Not Ready Yet—Small Production Tends to Keep The Price Up—Steel Prices Are Also Well Maintained

BUSINESS has not improved in the iron, steel and machine tool market during the week, nor are there indications of any immediate recovery. This is stating the worst at the outset, because several dealers report that they have some encouraging inquiries now that should result in business later on.

The New York tool market does not look for immediate reductions in prices. Makers are putting through such a few machines now that their costs are going up instead of down because the few tools going through have to bear the overhead which was formerly distributed over a much larger number. Neither does the Pittsburgh market look for much in the way of reduction in the prices of steel. Only in a few cases does it seem likely that 1921 will have a better price than that which is now quoted. The Corporation mills continue to produce well, while many of the independents are down.

The steel warehouse business is rather quiet in Canadian centres, and great care is being exercised by buyers generally. Even boiler tubes, which generally sell very freely at this season of the year, are being taken on only for pressing repairs, and several cases are reported where the policy of "making it last" is being pursued.

Small tools are also being bought sparingly, and users are getting them only as they are needed. Railroads have been placing some orders in this line during the week.

The scrap metal dealers are getting no new orders and what business they are doing is simply on filling old contracts. Buyers, they claim, are taking opportunity of every defect in a car to refuse delivery, while in times when things are going well and the material is wanted, nothing is heard about such defects. Prices which dealers would pay for old material are down again this week, but it makes little difference as there are no consumers in the market at any price.

## "WATCHFUL WAITING" IS THE ATTITUDE OF MANY BUYERS

Special to CANADIAN MACHINERY.

MONTREAL, Que., Jan. 13.—Mists of uncertainty still enshroud the industrial atmosphere, and until these have cleared away the sunshine of activity will be prevented from giving light to many who are now striving to see the return of the normal business day. On nearly every hand one sees the waiting attitude, everyone apparently deferring buying until lower prices have been announced. What is really expected in this direction it is hard to define. Many expect to see a drop in a week from a position which required years to reach. To avoid serious consequences it is necessary that any adjustment to pre-war, or even near it, must take many months before a satisfactory and healthy condition can be attained.

### Gradual Improvement Looked For

While there are those in the trade that think prices on steel lines must be further reduced before consumers will be influenced into buying on an extensive, or even a moderately liberal basis, many of the dealers state that it is not likely that present quotations will be materially changed for some time. "Prices are about as low as they can go. Some slight reductions may be made in some lines, but nothing to speak of. Selling prices are based on cost of production and present quotations are as low as existing circumstances will permit." The dealers further stated that it could not be expected that trade would show any marked change so early in the year, and, as a matter of fact, they did not anticipate any heavy buying for several weeks. The statement of another merchant indicated that trade, though far from brisk, was nevertheless of an encouraging character. The stock on hand was possibly less than normally carried, but much of it was purchased at figures higher than those now obtaining. This is especially true in regard to high speed steels. "We have some in stock now that cost us a dollar a lb. and we would willingly dispose of it at 75 cents. There is very little demand for this steel at the present time. The movement of carbon and cold-drawn steels is fair, but below that usually recorded at thi period of the year." Before purchasin new stocks the merchants are adoptin every means to liquidate existing sup plies, even though it be accomplished a a loss. As one dealer remarked: "I is better to take a small loss now than greater one later on." It is the merchan that has been unfortunate in having heavy supply on hand that must take th heavier losses, but the logical thing i to get rid of the material as soon a possible, so as to be in a position to tak advantage of the market when the lov level has been reached. Local price quo tations are relatively the same, the higl rate of exchange acting as a barometer in maintaining these at the comparatively high levels.

### Prices Still Declining

Buying is still quiet in machine tool circles, but some dealers report an improvement over that of recent weeks. While the greater volume of business is done in small equipment, the movement of heavy tools is not dead. One dealer stated that he made quite a large deal last week, including some heavy tools. However, many factories are still operating light and taking on only such equipment and supplies as will tide them over the immediate future. Other plants have

resumed activities, on a conservative basis truly, but sufficient to create increased interest from the dealer's standpoint. The situation is still marked by declining prices in many commodities, and a falling market has seldom been a lodstone to draw out the buyer. Manufacturers are making inquiries, but actual sales are only made when materials are urgently needed. "We are not carrying heavy supplies of any kind," remarked a dealer. "We do not intend to, nor would it be advisable until a sounder working basis has been establisned. We have often found that on a falling market the purchase of material for stock has resulted in a financial loss before the goods are finally disposed of. For this reason we are only stocking sufficient supplies to cover the present requirements of our customers, which, for some weeks, have not been very great. Before May, however, we expect that conditions will have shown considerable improvement."

### Light Business With Prices Firm

The metal market enters on the second week of the year with conditions about as they have been for the past several months, with buying restricted to actual requirements and business light in nearly every line of activity. Warehouse stocks in this district are generally sufficient to meet only the immediate needs of the trade and few dealers have been caught with heavy supplies on hand. "Speaking generally," remarked a dealer here, "we believe that metals have attained the lowest possible level that can be reached under the present order of things. This is particularly true in regard to ingot metals, but in the case of semi-finished materials some further adjustments may take place, but this will be governed by future developments. In the case of virgin metals the adjustment was brought about much sooner than in other lines, due largely to the additional volume of labor involved in the manufacturing processes of semi-finished and finished products. It is a little premature to predict the trend of the year's activities, as nothing tangible has yet developed to give a definite tone to trade conditions, but it is safe to say that, apart from slight fluctuations, the metal situation will continue firm, if it does not take on additional strength." The copper market has become steadier, with a slight upward trend in prices. The uncertainty of the past few weeks has been replaced by a confident belief that prices in this metal have reached the bottom and early reports may indicate a rise in price quotations. Spelter and lead show a slight decline on a poor demand, the quotation of 8 cents for spelter and 7¼ cents for lead representing a drop of ½ cent and ¼ cent per lb. respectively.

## POINTS IN WEEK'S MARKETING NOTES

**New York machine tool dealers are of the opinion that price reductions are not likely to come until there is a greater volume of business in sight.**

—

**Scrap metal prices were marked down farther in some lines this week. Dealers are not getting any new business and nearly all of the trading that is taking place is being done on old contracts.**

—

**The complaint is still heard in several different lines, that contracts are being cancelled without any fair explanation. Many of these cancellations are not being accepted.**

—

**The automobile industry has sent word to one or two large shops, intimating their renewal of shipments on contracts which had been suspended for some time.**

—

**Pittsburgh claims that steel bars averaged 1.40c in the ten years 1904 to 1913, and were down to 1.05 in December of 1914. The presetn price is 2.35 at corporation mills. It is intimated that the market may find its real basis at 2 cents.**

—

**Most of the steel warehouses in district claim that they have gone through the high price stage safely, and are not too heavily stocked at the present time.**

—

**Boiler tubes are moving at a very ordinary rate for this time of year by being rather lighter than usual.**

## BUYING DONE IN CONSERVATIVE WAY

**Yards in Steel Business Looking Over Records Find They Have Little High Cost Stuff**

TORONTO.—Buyers are going ahead very carefully in any section of the iron, steel or machine tool market that one cares to consider—in fact, there are a number of the dealers who will dispute the words "going ahead" in this connection at all. It is easier, many firms report, to secure money for any legitimate undertaking than it was three months ago, but as in other times it is harder to get any buying movement under way.

It goes back to the position in which the manufacturer finds himself. He is still asked for a high price for anything he wants to secure in the way of raw materials, and he is curtailing his programme to conform to known and definite wants. He is not going to be caught again with a lot of high price stuff in his warehouse that he will have to write off.

Encouraging reports are coming of the re-starting of several of the firms that have been closed for the holiday season, and some of them for some weeks before. Some of the automobile shops are ready to open up in a small way as a starter, and expect that once they get under way they will be able to go ahead again and work up to capacity before many months pass.

### The Steel Market

Some of the merchants in the steel industry are busy now fixing up their own business for the year. It has been a time of reckoning for some of them to find out just how they stood in the matter of having cleared out their high-price material. Some of them have bought quite heavily from premium mills during the past eight months or so, and the getting of this material out of their stocks before the price broke was a matter of no small concern. Most of them, from what Machinery can learn, have come safely through the business, and have been able to keep their prices coming down to market levels by the mixing of high and low price material.

Boiler tubes should be better than they are now. Even in this line, on which deliveries are not too good, but buying is being cut closer than ever, and in some cases where in ordinary times repairs would be made, it is being allowed to "get along" for the present.

Merchant bar material is not moving in much volume. The open season may have helped a little, but for the present buying is small and for immediate requirements only. Some of the larger agricultural makers seem to be rather conservative in their programmes, and are not taking on the stock they generally are at this time of the year.

There is a fair business being done in sheets, and no change has been made in price. Plate is not called for extensively just now, and can be secured readily from existing stocks.

### The Steel Contracts

One of the steel merchants in discussing the keeping of contracts and the adoption of the policy that "A Bargain Is Binding," claimed that this could be made effective only when both sides to the contract were making a serious effort to live up to it. "During the past year," he claimed, "we were under a so-called contract with the mills to buy from them, shipment to be made at their convenience. When it comes down to real facts, this business of mill convenience never arrived, and we got no material at all during the time when we were very much in need of it. A a

general thing, the keeping of contracts should be insisted upon, but the contract in the first place should be of such a nature that it is not a jug-handled affair that simply binds the buyer not to send his business to any other mill, without giving him a corresponding assurance that he will get as good service as he can get elsewhere."

### The Scrap Market Dull

The scrap market showed a little life this week—in fact enough to stimulate one of the dealers to rise up and mark down the list we have been publishing for some weeks past. Zinc, heavy and tea lead, aluminum, heavy melting steel, malleable scrap, No. 1 machine cast iron, car wheel, machine shop turnings, stove plate and cast boring were all marked down to lower levels.

There is very little business being done, and all that is under contract, with no new contracts being made. When old contracts run out there is nothing being done to renew the tonnage they represent.

Buyers are more particular now than they have been for many months, is the way one dealer sized the thing up. He claimed that instead of cancelling contracts, they came about it another way in a good many cases. Were there anything wrong at all with a car of scrap metal, the thing would be rejected outright. Many of the buyers were doing this because they did not want to take on the tonnage for which they contracted, neither did they want to come out and try for a cancellation. In ordinary times, or when the material was much wanted, there would not even be a complaint over a car that calls for a reject now. This dealer was certain that some of the users were going over the cars with a fine comb and a glass looking for defects or departures from classification.

# STEEL PRICES WELL MAINTAINED BUT SOME LINES MAY COME DOWN

Special to CANADIAN MACHINERY.

PITTSBURGH, January 13.—Production of steel ingots in December was at the rate of about 31,000,000 gross tons a year, this comparing with a rate of about 36,300,000 tons in November and an average rate during the first nine months of 1920, when demand was very heavy, but when there were very serious operating difficulties, of about 42,000,000 tons. The actual production in 1920 was 40,000,000 tons or a shade more.

Actual capacity of the industry, given reasonably favorable working conditions, such as always obtained prior to November, 1916, but which have been very rare since then, is about 52,500,000 tons or about 22,500,000 tons for the Steel Corporation and 30,000,000 tons for the independents. The mills did not operate in December in these proportions by any means, as the Steel Corporation still had good order books and indeed increased its operations slightly, by reason of having greater supplies of coke, while the independents had almost run out of orders. The corporation operated in December at about 92 per cent. of capacity and the independents at about one-third capacity. As nearly as can be estimated, in December the Corporation produced ingots at the rate of about 21,000,000 tons a year, while the independents produced at the rate of about 10,000,000 tons. Independent mill operations have been declining continuously and thus are now at a materially lower rate than the average of December, probably between 20 and 25 per cent. of capacity or at 6,000,000 to 7,500,000 tons a year.

The greatly different positions of the Steel Corporation and independents is shown in another way by the record of blast furnaces. In December independent steel works and merchant furnace interests blew out 55 blast furnaces and blew in none, while the Steel Corporation blew out only one, and blew in five.

### Production Prospects

At the present moment steel ingots are being produced at the rate of about 28,000,000 tons a year. Of course, one would like to see prospects of the rate of production beginning to increase at once, but obviously that cannot be expected. In the first place, buying is very light, indeed, while from day to day old business is being completed. In the second place, a rate of 28,000,000 tons is precisely two-thirds of the 42,000,000 ton rate that obtained during the first nine months of 1920. Nobody can be so ignorant of general conditions existing, as compared with those in the major part of last year, to believe that the rate of steel consumption is decreased by only one-third. Finally, it is known that some of the steel now being shipped to dealers and consumers, and being accepted willingly by them, is not being consumed. The steel is accumulating. Obviously these buyers will not, for any length of time, continue to accept more steel than they are consuming.

Hence further decreases in production of steel may be expected. The question is when increased buying will have proceeded far enough to take up the slack and convert decreasing production into increasing production. In well posted and conservative quarters it is confidently predicted that there will be a decided improvement in buying of steel products some time in March, more likely in the second half of the month. It may not be until some time afterwards that the rate of steel production will back to the present rate, but it wou not require much to put the industry better shape than it is in at present.

### Prices Present and Prospective

Steel prices may be described as b ing well maintained, but that is real not saying much since so little busine is moving that there is scarcely any o portunity to cut prices. It may be sai however, that most mills are altogeth averse to cutting prices. It was or thing for the independents to redu their prices to the Steel Corporatio level. It would be another thing alt gether for them to cut the Steel Co poration prices. The independents woul of course like to operate their plants i full, but there is no chance of thei being able to do any such thing for th present. A good way to put in the tim is to reduce production costs, and period of idleness is not altogether ob jectionable, having some advantage Undoubtedly there will be competitio between some of the smaller mills, re sulting in price cutting, but there wil be none of this on the part of the Stee Corporation or several of the large in dependents.

A fairly steady market, therefore, i to be expected for some time to come perhaps for only a few weeks perhaps for several months. Eventual ly, without doubt, prices will be lower Some manufacturers virtually admi this. Others do not, but that is presum ably from policy or habit. There is am ple proof that steel prices will be low er. As noted above, production durin the first nine months of 1920 was at th rate of about 42,000,000 tons of ingot a year, and that was only 80 per cent of capacity. A greater output could no be realized because there were physica difficulties in the way, the chief of whic was shortage of fuel. Thus to employ the full capacity consumption would have to be one-fourth greater. It cannot be argued that physical disability will stand in the way, for when industry becomes active again it is going to be on an efficient basis. There will not be a full demand unless everything is functioning smoothly. It is a settled fact in the present readjustment that in future all industries will have to be content with moderate profits. When the Steel Corporation operated at well under capacity in 1920 it reported large profits, and practically everyone is convinced that the accounting methods were so conservative that the profits were really larger than were reported. Accordingly, very large profits would be yielded on present prices with full operation and with the reduction in costs from the present level that is now regarded as certain. Hence selling prices will be lower, but they will hardly be lower until costs have been reduced and until there is prospect for a moderately full operation of industry. Merchant

steel bars, the most prominent product of the steel industry, averaged 1.40c in the ten years 1904 to 1913 and were down to a minimum of 1.05c in December, 1914. The war control price was 2.90c and the present price, that of the Industrial Board and of the Steel Corporation, is 2.35c. According to whether the reduction in costs is mild or drastic, and the wait for large orders to be offered is short or long, the steel bar market will probably turn on either about 2.00c or 1.80c. Of course, definite predictions as to actual quotations cannot be made, and figures are mentioned here merely to assign a definite measure to the estimate of the forces that will be at work.

# TOOL DEMAND TOO LOW TO PERMIT OF ANY LOWER COSTS

Special to CANADIAN MACHINERY.

NEW YORK, January 13, 1921.—While so far as the machine-tool trade is concerned there was little indication of improvement in business in the first week of the new year, there were a few marked instances of betterment in the general business situation, which was reflected in a more hopeful feeling in machine-tool circles. Other lines of industry must recover from the depression before the buying of machine tools on a fairly normal basis can pick up. There is a slightly better inquiry for tools, but orders are still extremely scarce.

One reason for the improvement in the general business situation is that prices of many basic commodities are believed to have touched bottom. In some instances they are down to or below the pre-war level, and buyers are showing a little more confidence in placing orders. Moreover, the liquidation in retail stocks is now going on more rapidly, and this will be reflected soon in orders for jobbers and manufacturers in various lines.

The price situation is one that is somewhat disturbing to the machine-tool manufacturers. Buyers point to the fact that the liquidation which has gone on in other industries has, as yet, scarcely touched the machine-tool industry. It is true there have been some price reductions, but the majority of tool manufacturers are not reducing prices and have no apparent intention of doing so at present. Some of them say that when a sufficient amount of business comes into sight to justify lower prices they will consider making them; others say that there must be considerable reduction in their manufacturing costs before they will reduce prices. While pig iron and steel are cheaper, any saving thus effected by the machine-tool manufacturer is more than offset by the present low production. As fewer machines are being turned out each machine must stand a larger proportionate part of the general overhead.

Some machine-tool manufacturers have assured their machinists and other highly skilled mechanics that there will be no reduction in their wages. It is recognized that skilled machinists did not receive before the war a wage commensurate with their skill and the time required by them to learn their trades. There seems to be a general disposition to accord machine shop artisans a better wage than they received before the war.

Taking all of these factors into consideration the prospect of a very large reduction in machine-tool prices does not seem encouraging from the buyer's viewpoint. Just how the situation will work out is for the future to determine. It seems improbable that there will be many price reductions while the demand for tools is at its present low point.

## PIG IRON TRADE

Although the pig iron market entered the new year at a low ebb, the feeling among dealers is inclined to be optimistic.

A prominent valley producer in the Pittsburg district announced at the open of business this year that they were willing to sell basic pig iron at $30 valley, and bessemer and malleable at $32 valley. No sales of consequence are reported. There have not been enough sales of foundry iron to have a clear cut market but some furnaces would sell at $33 or less.

A number of inquiries have appeared this week on the Cincinnati market, and hope is held out that the slump will soon be over. There has been a withdrawal of some of the resale iron which was glutting the market.

On the Birmingham pig iron market, release orders have been encouraging, but they still fail to cover much of the help up tonnage.

There is a more optimistic feeling on the Buffalo market. It is believed that buying will soon become active though furnace operation is no livelier. No. 2 plain 1.75 to 2.25 silicon is quoted at $34 to $35 f.o.b. Buffalo and basic at $36.

New York has practically a lifeless market. Resale iron continues to be an important factor.

Furnaces in the Cleveland district have started the new year with a large tonnage of last half iron carried over on their order books. Pig iron will be further curtailed in this district by the shutting down of the Ford Motor Co. Furnaces are quoting foundry iron at $35. Several additional stacks have blown out during the week.

Inquiries on the Chicago market, though small, are more numerous and the passing of the old year resulted in the withdrawal of some resale offerings. Both these facts give the market a more cheerful tone.

## TO START WORK ON THE CONTRACT

**Ontario Firm Will Begin on Work For Auto Concern That is Restarting**

The announcement that the large motor concerns in Detroit are again manning up with the purpose of resuming operations is not without a note of encouragement to Canadian manufacturers.

The manager of a large plant in the Niagara peninsula told Canadian Machinery that a large order on which cancellation had been refused as far back as September had been practically ordered resumed, and that a representative of the motor parts institution concerned was calling on all plants interested in Western Ontario, advising them that orders would stand and at prices agreed upon.

It would appear that busy times are not far distant. Reports from Detroit indicate that car orders are coming in in fine volume.

## CUT THE WAGES IN STEEL MILLS

**Big Firms Make Reductions That Will Amount to 25 Per Cent**

JOHNSTOWN.—R. M. Custer, vice-president of the Cambria Steel Company, has announced a reduction of wages amounting to 25 per cent., and that all but a few of the smaller departments will be closed down for at least two weeks.

Extensive declines in the selling prices of iron and steel made necessary the wage reduction, according to notices posted on all bulletin boards in the big plant. These notices said that all Cambria workmen, whether employed by the hour, day, turn, tonnage or piece work, are included in the wage revision, as well as all salaried employees.

Executive officers of the principal independent steel company here, when informed of the wage readjustment in the mills of the Cambria Steel Company at Johnstown, frankly stated that drastic reductions would be announced for the Pittsburgh mills.

They took the position that while production costs were on the present basis there could be no stability in the steel market, and it was proposed to bring about the complete readjustment of wages as soon as possible.

SYDNEY.—A 20 per cent. cut in wages, effective January 17, has been announced by the Dominion Iron & Steel Co. The reduction will affect approximately 5,000 men, of whom about 2,100 are temporarily laid off.

# $150,000,000 in Steel From the U.S. to Canada

## Lloyd Harris Brings Up an Important Point in Address at London—What Has Been Done Along These Lines to Make Use of The Canadian Iron Ore Deposits?

LONDON,—Lloyd Harris, of Brantford, addressing the Canadian Club at a banquet at the Tecumseh House, announced that Canadian scientists have succeeded in developing a method by which Canadian refractory ores can be treated. He explained that, because of the difficulties of ore treatment and the fact that practically all coal now comes to Canadian mills from American mines, numerous experts had reported that the Dominion has not the basis for a steel industry. This country, he said, imports $150,000,000 worth of steel from the United States every year, and as a result the difficulties of exchange are rendered more acute. Efforts are now being put forth to devise some method of standardizing steel forms so that Canada's wants may be supplied at home. To this end an Australian system of standardization is being studied.

### Use Electric Furnace?

In connection with this matter, Canadian Machinery put the matter up to several men who have experimented largely with the electric furnace. W. F. Sutherland, who has worked in conjunction with James W. Moffat, M. E. I. C., answered the point on the reduction of iron ores, as follows:

In the manufacture of steel, the electric furnace has won a place its many advantages justly entitle it to, but in the field of ore reduction past processes and equipment have not proved commercially successful unless under exceptional circumstances. This is due to a number of causes, chief among which is the inability of any of the processes to make steel directly from the ore with any degree of uniformity or economy. And while in many cases a varying amount of carbonaceous material, coke or charcoal has been saved the extremely large amount of power required has more than counterbalanced any saving in fuel.

The reduction of iron ores in the blast furnace is a process which is fairly well understood to-day and with its adjuncts, the blast furnace is a comparatively cheap mechanism to run. The carbon monoxide content of the gases given off in reduction is of use in preheating the blast and also for the furnishing of power to steel mills and other portions of the plant not directly connected with the blast furnace itself.

The consumption of fuel in the blast furnace is however high in that approximately three to four times as much fuel is charged as is required to supply the reaction heat, the remainder being used to heat the charge, melt the slugs and metal and besides unavoidable losses, heating the large amount of air which has to be supplied. This latter item is a very considerable one and may be set down almost as a total loss.

### More Need for Economy

With the ever mounting price of coal and its resulting coke, fuel economy is very important, particularly so where suitable coking coals are either nonexistent or scarce. For this reason it is to be expected that direct processes, saving in coke and using electrical energy for certain stages of the process should meet with favor.

An important advance both in ferrous and non-ferrous metallurgy has recently been made in a process devised by James W. Moffatt, M.E.I.C., of Toronto, Ont., and the production of iron and, steel from ore direct, has been brought appreciably nearer solution.

In this process for which patents have been obtained in the United States, U.S. Patent No. 1,294,514, and principal foreign countries use is made of two separate and discontinuous step in two separate types of apparatus. The ore is first finely ground and if necessary concentrated and is then charged into a reduction furnace. Here the carbonaceous reducing material is added and reduction to iron sponge or finely divided and porous metallic iron takes place. This sponge is then charged directly into an electric furnace of the ordinary type and is there melted down by electric heat. In this melting down the electric furnace is used through the certainty with which a reducing atmosphere can be obtained and through the desirable qualities of the steel or other metals obtained by its use. The duplexing of the electric furnace with the reduction furnace and the avoiding of the re-oxidation of the sponge in its transference from the one to the other are the basic features of the process patents obtained. Particular stress is laid on the prevention of re-oxidation since nearly all metals in a reduced and finely divided state will oxidize very readily at even moderate temperatures.

### Cheaper Than Open Hearth?

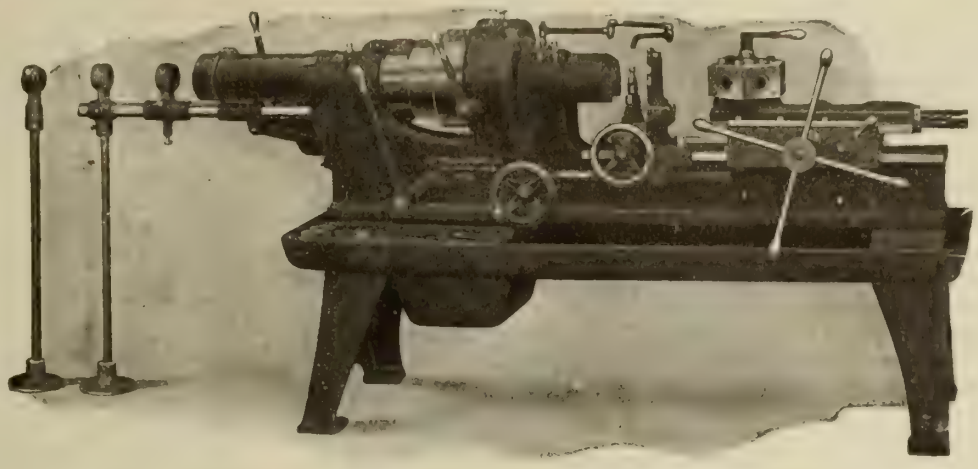
The process as worked out in practice lends itself to economical results and is quite comparable to other present day methods in this respect. Given the right conditions it is possible to produce steel more cheaply than can be done in the open hearth.

This economy is obtained in great measure through a reduction furnace which has also been patented by Mr. Moffat, U.S. Patent No. 1,348,889. As mentioned above the blast furnace requires a very considerable volume of air for its continued operation and muc heat is lost through the escaping gases of which the nitrogen in the a forms no inconsiderable amount. In th present reduction furnace the carryin on of reduction and the supplying of th heat for the reaction are kept separat The reduction is carried on in a reto heated on the exterior and the gase given off consist entirely of carbon mon oxide with a certain percentage of ca bon dioxide only. They are thus of hig heat value and containing no diluent such as nitrogen are comparatively ric and of smaller volume. Theoretically the amount of carbon monoxide give off is sufficient in its heat value whe burned to supply the heat necessary fo the carrying on of the reaction and i the present instance provision has bee mode for their utilization in this manner In practice a small amount of heat ha to be supplied from another source, bu the total fuel consumption is limite to a slight excess over the theoretica amount required for reduction togethe with the small amount of auxiliary fuel The reduction of the ores by this metho will show a very much decreased cost fo fuel when compared with the blast fur nace.

### Can Be Charged Hot

By the using of the more expensive electrical heat in the final melting down only, a marked saving in power cost also results. The ordinary six ton electric furnace working on alloy or plain carbon steels, running two slags will have a power consumption of about 700 to 800 k.w. hours. In the present case a saving will be effected over this amount since the iron sponge resulting from the reduction operation can be charged hot.

Furnace operation is also smoother and, on starting each heat, inductive troubles with consequent lowering of power factor, and short-circuit conditions are absent.



An interesting feature of the process is its extreme flexibility. With carbon control as provided for, irons can be made varying from pig iron through high carbon steel to a practically carbon free metal of extreme softness. The reduction furnace is also capable of roasting operations and the elimination of sulphur is thus quite easily carried out. This feature is of advantage in the treatment of many ores unavailable at present except by roasting and a subsequent briquetting operation. Since in any case crushing is necessary for this direct process, concentration is easily carried out and a large number of ore bodies too lean for economical working

# Warner & Swasey Screw Machines

For large output and close limits—If you are figuring on screw machine work you can depend on W. & S. machines being right for the job.

**We can supply you from stock immediately.**

## The A. R. Williams Machinery Company, Limited

ST. JOHN, N.B.
WINNIPEG, VANCOUVER

*If It's Machinery—Write "Williams"*

64 Front Street West
TORONTO

CANADIAN MACHINERY wants a representative in every town and city where there is a metal working plant or large machine shop.

We require first of all the ability to demonstrate to mechanics the value of reading technical journals in general and CANADIAN MACHINERY in particular, and to secure their subscriptions.

Second—we want men who can tell news when they see it. Not necessarily men who can write, but men who are alert for news, and who will give us the facts, briefly and plainly.

We will pay you liberally if you can handle this work for us in your city.

# The Week's Events in Montreal Industry

Lieut.-Col. Gardiner, of Robt. Gardiner & Son, Montreal, who has been confined to his home for the last three weeks by illness, is now reported to be progressing favorably and sitting up, and it is hoped that he will soon make his reappearance down town.

---

Mr. Roy Wolvin, president of the British Empire Steel Corporation, is still in London, but is expected back in Montreal about the end of this month, and at that time it is expected he will have some announcement to make regarding the form which the merger will eventually take.

---

The Watt Machinery and Equipment Company are now well established in their new offices at 344 St. James St., Montreal. They have ample space for carrying large supplies and in a very brief time will be in a position to meet every requirement for machine tool equipment and sundry supplies.

---

The Angus shops of the Canadian Pacific Railway in Montreal have again resumed operation after a shut down of about ten days. It has been stated that work has been continued with the same staff as before the holidays, the number of employees now engaged being around 5,500. The wage scale remains the same as that in force before the suspension of activities.

---

The Holden Company, of 354 James St., Montreal, are distributing to the trade a very attractive calendar of the Chicago Pneumatic Tool Company. The calendar is printed on coated stock, 12 inches wide by 24 inches deep, the upper section of each page carrying a large reproduction of one of the applications of one of the company's air-operated tools. The entire calendar is neatly arranged and well deserving of a place in any engineering office.

---

At a recent meeting of the Montreal Automobile Association it was decided to change the name to that of the Montreal Motorists' League. The Board of Directors, under the leadership of president J. D. Chesney and Vice-president Malcolm LeMieux, are making efforts to increase the membership to 5,000 during the coming year. In the absence of T. C. Kirby, the secretary-treasurer of the Association, the duties of the office will be looked after by Director J. K. Blyth.

---

William Petts, travelling mechanical inspector of the Ocean Accident and Guarantee Corporation, died last week after a long illness. Mr. Petts was born in England 64 years ago, coming to Canada in 1882. He has occupied quite a number of prominent positions, his first here in Canada being foreman for the railway machine shops in Montreal. He was about 12 years with the Laurie Engine Company, and with the C.P.R. before entering the services of the Ocean Accident and Guarantee Corp.

---

A course of lectures on Industrial Chemistry will be one of the features of the present season at McGill. This series of addresses is designed to be of interest to anyone desiring scientific information applicable to their own occupations. The lectures will be conducted by specialists from Montreal manufacturing plants, and the talks will be as free as possible from technical language, and the subjects will cover chemical processes in use in plants manufacturing sugar, pulp and paper, paints and varnishes, Portland cement, steel, lead and other products.

---

Following the closing down of the large blooming mill of the Nova Scotia steel plant some three or four weeks ago, the remaining departments of the works suspended operations last week. The action of the management in this respect did not come as a surprise as the employees have been expecting some such move for the past three weeks, or since the stopping of the mill. With the exception of two spike machines and a few machines in the nut and bolt department, the entire plant will be closed for an indefinite period. In addition to affecting the workmen, it is stated that about seventy-five of the head office staff have been notified that their services will not be required after the last of this month.

---

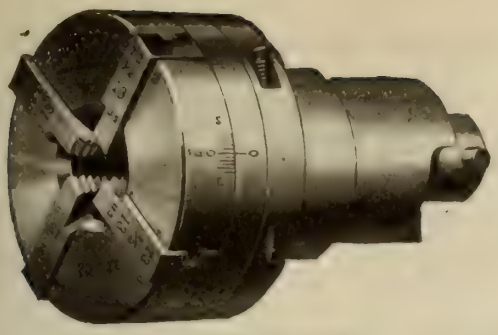
A demonstration of specially designed tractors for the removal of snow from the city streets was given before the city commissioners of Montreal last week. The exhibition was given on the Champ de Mars, the three manufacturers demonstrating their machines being the J. T. Tractor Company of Cleveland, Ohio; the Cleveland Tractor Company of Montreal; and the Holt Manufacturing Co., of Peoria, Ill. The operation of the machines is on the same principle as the steam shovel, the work being accomplished by the caterpillar spikes breaking up the snow, and the weight of the tractor pushing it aside, the snow being then lifted and placed in cars or carts. One of the machines was so small that it could be worked to advantage on the ordinary sidewalk.

---

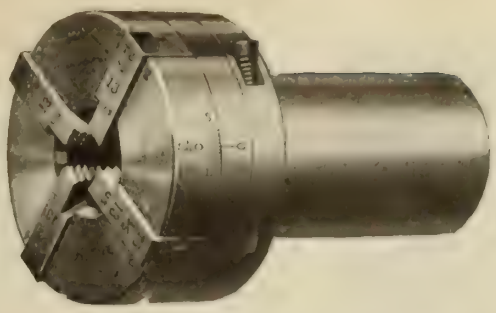
William Beardmore and Company, of Scotland, have opened a Canadian office at 385 Beaver Hall Hill, Montreal. This firm carries on an extensive business in many lines of engineering activity, manufacturing steel shaftings and forgings of all sizes types and axles, small tools, jigs and fixtures, locomotives of every description, lapwelded furnaces and flanging work of all kind. They also plates and sections, and complete boilers of every type and size. They are builders of steam, turbo, Beardmore-Tosi Diesel and Beardmore crude oil engines, centrifugal and semi-rotary wing pumps. They are also naval constructors, having built H. M. S. Raleigh and other war vessels. They are now installing a semi-Diesel crude oil engine of 320 B.H.P. in one of the new Hudson Bay vessels.

---

**$15,000,000 IN STEEL**

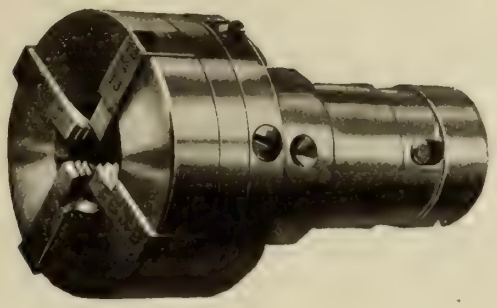


Continued from page 58



to-day will thus be rendered available With the depletion of the Minnesota and other high grade beds the leaner ores of the country will become of more importance in the coming decade and a process which can use concentrates without further treatment will thus be of much value in metallurgy.

The reduction of iron ore without fusion or its manufacture into sponge dates back into the dawn of the iron age. The primitive man probably first made it in his crude forges, and the Catalan forge, in common use in Europe until comparatively recent times, made a form of sponge. Later attempts at direct processes also made use of sponge iron to some extent but difficulties in the prevention of re-oxidation, together with the comparatively expensive nature of the processes, prevented their commercial success.



While the process will find its greatest field of usefulness in ferrous metallurgy it is equally adapted to non-ferrous metals and where such can be obtained in the oxide form, and are suitable for reduction by this means, their economical winning will be possible.

The successful outcome of fifteen years' research on the part of Mr. Moffat should prove of considerable value in the utilization of Ontario iron ores, many of which can only be successfully treated by means of concentration and, in the case of siderate ores, by calcination. It is interesting to note that only recently the utilization of domestic ores has received consideration at the hands of the Advisory Research Council and that Professor Stansfield has been carrying on research under grant from the council with the some end in view during a portion of the past year. Attention is drawn by Mr. Moffat to the fact that his patents are basic and cover any metallizing furnace in combination with any electric furnace for the production of iron and steel direct from ore by the sponge process.

# Geometric Solid Adjustable Die Heads

When one uses the word "ONLY," he needs to be sure of what he is talking about. With confidence we use the word in saying that a Geometric Solid Adjustable Die Head, fitted with a set of milled dies, is the only solid die head that will back off without stripping the thread.

Geometric Solid Adjustable Die Heads may be fitted with either a releasing shank, plain shank, or with special shank for the Gridley Automatics. The releasing shank permits the head to disengage from the shank upon completion of the thread. The plain shank fits the head for use on the turret of a lathe or on a live spindle, such as a drill press.

Apart from the fact that it is not equipped with the self-opening feature or the roughing and finishing attachment, the Geometric Solid Adjustable Die Head is the same in principle and construction and will do equally as accurate work as the other styles of Geometric Die Heads.

**Whatever the requirements, there is a type of Geometric Die Head best adapted to the work.**

PERSONAL AND TRADE NOTES

## EXPECT MORE TRADE IN 1921

**Convention of the International Business Machines Finds Canada In The Lead**

Optimism was the keynote at the Convention of the Canadian sales force of the International Business Machines Company, held at the offices of the Company, Royce and Campbell avenues, Toronto, in the week of January 3rd, 1921. "A fifty per cent. increase in business in 1921" is the task to which they have addresed themselves and not a few expressed the conviction that even this mark would be passed long before the close of the year.

About 75 salesmen in all were in attendance at the convention. They represented the three divisions of the company—International Time Recorders, International Dayton Scales and International Tabulating and Sorting Machines.

Figures presented at the convention showed that the Canadian organization held all sales records for 1920 against the sales forces of the American firms manufacturing similar products. In fact, the Canadian organization has led the entire world in sales, on percentage of quota, for four successive years.

The factory organization did itself proud in decoration to welcome the boys from the field. When the latter arrived from all parts of Canada—from Vancouver to Newfoundland—they were greeted by a group of pretty office girls, who pinned a buttonhole bouquet on each of their lapels, and who further had prepared a song applicable to each member of the sales force.

F. E. Mutton, vice-president and general manager of the International Business Machines Co., Limited, is proud of his sales force and advises that not only he, but the entire sales organization never were more optimistic as to the future.

The convention was addressed by Thomas J. Watson, president of the Computing Tabulating-Recording Co., of New York; Joseph E. Rogers, general manager of the Tabulating Machine Company, New York; S. M. Hastings, president of the Computing Scale Company of America, Chicago; S. Spahr, general manager o fthe Computing Scale Company of America, Dayton, Ohio.; D. C. Wells, general manager of the Moneyweight Scale Company, Chicago.

Monday evening, January 3rd, was spent at a theatre party at Shea's Theatre, and Tuesday evening Mr. Mutton gave an exclusive banquet to the members of the I.B.M. Club, comprised of men who lead the entire organization, at the King Edward Hotel. Wednesday evening was devoted to a supper dance to the entire organization at Masonic Hall, at which some novel vaudeville features added materially to the merriment. Friday evening closed the convention with a banquet at the King Edward Hotel.

## AUTO COMPANIES TO REOPEN PLANTS

**Men Being Taken on Gradually, Depending on Demand for Cars**

Detroit.—That the renewed tendency of the public to buy whatever it needs is having its effect on Detroit industry was indicated Saturday, when the Liberty Motor Car Company announced it would renew production on a small basis January 17.

According to officials, the reopening of the plant is based entirely upon the demand for cars. Three hundred men will be put to work at first, and this number will be increased after the New York show, which is expected to stimulate sales.

Three hundred employees of the Chalmers Motor Company, laid off December 24, will go back to work Monday morning or some time next week, according to employment officials of the firm.

The Studebaker Corporation intends to open its Detroit plant on a three-day schedule Monday morning. A limited number of old employees will be given work, and a plan to build up to normal capacity from this nucleus has been adopted, said James E. Spencer, assistant to the vice-president.

**For Gold Work.**—Wayne Forge & Machine Company, Toronto, have just completed a special furnace for annealing gold. The gold in strip form, is fed in the furnace and comes out the back, the operation being continuous. This furnace is about seven feet in length. It was built to the order of a local jewelry manufacturer.

## Trade Gossip

**In New Premises.**—Elliott & Whitehall, manufacturers of small tools, Galt expect to be in their new building by Spring.

**Put in Machine Shop.**—The MacFarlane Enginering Co., Paris, have installed a well-equipped machine shop in connection with their foundry.

**Starting in Kitchener.**—The majority of the Kitchener industries will be in operation, after having been closed during the holiday season. With the exception of a few furniture factories, the industrial activities of the city will again be normal. Owing to the furniture exhibition here this week, most of the factories will remain closed until the seventeenth.

**Re-open Plant.**—The Studebaker Corporation of Canada, Limited, Walkerville, reopened on Monday morning with a force of 200 men, it was announced by Edward Mackie, plant superintendent. The company has retained 100 men during the inventory and will again take on another 100 men, all of whom were formerly employed. Married men will be given the preference in hiring back old employees.

**British Trade.**—Mr. T. R. Mason, a representative of a Sheffield steel concern who is visiting Canada to gain an intimate knowledge of the trade conditions here, said that Great Britain was reassuming and recapturing trade which it had lost during the war and was even going into new fields in the face of strong competition. Business gloom is vanishing in England, and within five years England will be farther ahead than it ever was.

**Plants Re-open.**—The Wabasso Cotton Company and the Tidewater Shipbuilding Company, at Three Rivers Que., reopened their doors after a week's shutdown. All the men were taken back. Wages were reduced 10 per cent. at the Wabasso. The St. Maurice Paper Company have reduced the wages of their lumber cutters to $60 and $75 per month. The shutting down of the Wayagamack Pulp & Paper Company's plant has been postponed for a few days. A poster advises the men that the plant will close its doors on or about the 15th of January for a short time. There will be no reduction in wages.

# ENGINEERING

The National Castings Ltd., will build a foundry at Belleville, Ont.

A by-law for $75,000 for fire apparatus was carried at Fort William.

Ratepayers of Perth, Ont., carried a by-law for a new hospital there.

The ratepayers of Ford City, Ontario, have passed a by-law for technical school.

A by-law was carried to provide $135,000 for a new school for Terrace Hill, Brantford, Ont.

Tuttle-Bailey Mfg. Co., Bridgeburg, Ont., are making arrangements to enlarge their plant.

Alfred LePage, 1775 Georgia St. W., Vancouver, B.C., will erect a storehouse and machine shop.

The property owners of Kingston, Ont., passed a by-law to grant a site to the Kelley Driver Co.

Reynold Moore and Benz Co., Ltd., Higgins Ave., Winnipeg, contemplate the erection of a factory at Vernon, B.C.

The Electric Foundries Ltd., Tudhope Knox Building, Orillia, Ont., will build a foundry at a cost of $20,000.

London, Ont., is to have a Home for Incurables, and a new Children's Hospital. By-laws were passed by the ratepayers of $50,000 for each.

R. N. Irvine is to erect a three-storey building at 340-4 Yonge street, Toronto, for the Thornton-Smith Co. Estimated cost, $100,000.

Tenders will be called in March for the erection of an addition and alterations and improvements to the Sheldon Hotel, Blenheim, Ont.

The general contract for erection of a garage on Lansdowne Ave., Westmount, has been awarded to Fussing & Jorgensen, 6 Durocher St.

Niagara Glass Co., 40 King St., St. Catharines, have purchased the building at 220 St. Paul St., which they will alter to suit their requirements.

The Consumers Gas Company, 19 Toronto St., Toronto, are erecting an addition to their office building at a cost of $50,000. Work will commence shortly.

The Dominion Bridge Company have received the contract for steel in connection with the erection of a large hotel for the Mount Royal Hotel Company, Ltd.

The contract for the soldiers' pavilion and reception hospital at Selkirk, Man., was awarded to the Carter-Halls-Aldinger Co., Ltd., Winnipeg, the price being $469,000.

Plans are being revised by Pratt & Ross, architects, Electric Rly. Chambers, for addition to show rooms, to cost $15,000, for the Manitoba Motors Bldg., 293 Garry St., Winnipeg.

# USING PROFITS TO WRITE OFF HOLD-OVERS FROM WAR YEAR

RE-ORGANIZATION of their business program to meet changing contions has occupied the attention of a good many firms during the past few weeks. A feature of the work has been the wiping out or writing off, or erasing from memory—whatever phrase suits best—of overhangs or adverse items that were handed down from the strenuous days of war. Many of these matters could not possibly have consideration in the warp and woof of business as it is being shaped to-day, and are best forgotten. At the same time firms who have the right perspective are strengthening their sales forces and selling equipment, for all are agreed that strenuous and more competitive days are ahead—if they have not already arrived.

"To wipe these things off and forg about them, so as to start anew wi a clean slate, is the only business-li method," said B. J. McCormick, of t Canada Forge, Welland, to Canadi Machinery, recently. "There is a han cap in left overs and the same, it seer to me, applies to conditions confronti the dealer as well as the manufacture Cash on hand is more useful to the dea er than shelves full of stagnant stoc bought at prices which the public will n meet, for ready money makes possib the purchase of new goods at prese values and puts the merchant on an u to-date selling basis. There is som times better strategy in taking a lo than in sitting tight. A strategic lo nowadays seems to be essential to th most effective offensive."

Ratepayers of Midland decided to grant a fixed assessment of $35,000 to Mason and Co., for the extension of their sawmills, and a similar exemption to Manley Chew for the construction of a fibre board plant.

Notice has been given to the effect that the Winnipeg assembling plant of the Ford Motor Company of Canada, which has been closed since November, will reopen on January 12. It is announced that no cut in wages will be made.

The unemployment situation is much brighter in Stratford as the local factories, which closed down for stock taking and the holiday season, have resumed operations with practically full staffs.

Anglin-Norcross Ltd., 65 Victoria St., Montreal, have received the general contract for extension to factory for the Standard Paint Co., of Canada, 52 Victoria Sq.

The contract for electrical work on $300,000 theatre being erected in Victoria, B. C., by the Famous Players Canadian Corp. has been awarded to the C. H. E. Williams Co., 509 Richards St., Victoria.

# PERSONAL

Mr. D. F. Griffith, sales manager of B. Greening Wire Co., Ltd., Hamilton, is in New York on business. He will be absent about ten days.

Mr. George Bertram, sales manager of the Lincoln Electric Company of Canada, is in Cleveland, Ohio, this week, on business.

M. H. Wood, who for the past year has been conducting a jobbing machine shop at Aylmer, Ont., has disposed of his interests there. Mr. Wood has removed to Toronto and is now on the sales staff of the National Electro Products, Ltd., manufacturers of oxygen and hydrogen gases for welding purposes.

D. M. McLean, formerly chief engineer of the Dover Boiler Works, Dover N. J., general sales manager of the I & I. J. White Company, Buffalo, N.Y etc., and for the past four years manage of the publicity department of the Can adian Ingersoll-Rand Company, Sher brooke, Quebec, recently left the latte company to assume control of C. & C Limited, Rock Island, Quebec, manufac turers of fancy biscuits and candies Mr. McLean's son, F. A. McLean, A.M C.M.I., and formerly with the Crocker Wheeler Company, Lackawanna Steel Company, McKiernan Terry Core Dril Company, etc., and latterly genera assistant publicity department Canadian Ingersoll-Rand Company, has been appointed as his successor.

# OBITUARY

The death occurred on January 7 of Edward G. Little, engineer of the local Hydro power plant, at Erindale, Ont.

J. C. Kennedy, C.E., died very suddenly at Owen Sound on New Year's day He was formerly city engineer of that city.

Charles W. McGuire, manager of the Imperial Oil Co., London, Ont., died on January 9th at his home, 799 Hellmuth avenue, following several weeks' illness from heart trouble. Mr. McGuire was one of the most prominent Masons in Western Canada.

**What's This?**—A wireless message from Moscow saying that a great many mechanics from Detroit, Mich., are now working in the Donetz coal basin of Russia has caused considerable speculation in diplomatic circles, coming after reports from Berlin to the effect that 4,000 United States citizens now in Germany are going to the same region to man the factories. Most of these men are said to be experienced in automobile construction.

# NEW CATALOGUES

**The Automatic Transportation Co., Buffalo, N.Y.,** have sent us several of their publications. These include bulletin 25, which describes their automatic tiering lifting truck; bulletin No. 26 which describes their automatic storage battery industrial trucks, tractors and engines, and a booklet entitled Conclusive Evidence, which shows copies of various letters received from satisfied customers. Another booklet tells the story of their type L electric lifting platform truck.

**The Cleveland Twist Drill Co., Cleveland, Ohio.**—A very useful handbook for drillers. This little volume is prepared for the use of drillers. The parts of a twist drill are first discussed, points of grinding are talked on, this including all the common errors. The third chapter is devoted to drill speeds and feeds, while chapter four is full of miscellaneous helps. The last chapter tells of some common errors and their results, while a few remaining pages discuss certain products.

**Armstrong-Whitworth of Canada, Ltd., Montreal.**—Brochure No. 11, which is devoted to A. W. non-ferrous products. This booklet illustrates various of their lines and particulars of the same.

**The L. S. Starrett Co., Athol, Mass,** have issued a new catalogue that contains information on about twenty-one new tools not included in previous catalogues. Some of the new tools included are a universal bevel protractor, a micrometer caliper gauge, a tool-maker's button, a metric micrometer caliper, and others.

**The Chicago Flexible Shaft Co., Chicago, Ill.**—Catalogue No. 56, dealing with gas and oil blast furnaces for the heat treatment of metals. A table is given showing the proper type of furnace for certain classes of work. Combination furnaces, high speed steel furnaces, barium chloride furnaces, bench oven furnaces, annealing tool and die heating oven furnaces, cyanide hardening furnaces and others are included in this book.

**The Langhaar Ball Bearing Co., Aurora, Ind.**—A catalogue dealing with Langhaar self-adjusting ball bearings. A complete description of this type bearing is given, also some illustrations of typical installations.

**The Canadian Atlas Crucible Steel Co., Ltd., Welland, Ont.**—A catalogue dealing with their various lines of tool steels. Various hints as to the working of the different steels are also given.

**The Landis Machine Co., Waynesboro, Pa.**—A very useful handbook for all operators of Landis threading machinery. Instructions for grinding the chasers is given. Care and operation of die heads for the different machines, certain don'ts, which should be read carefully, special threads and other interesting subjects are discussed in this valuable aid which is edited by C. F. Meyer and C. H. Kirkpatrick.

**The McDonough Manufacturing Co., Eau Claire, Wis.**—A catalogue devoted to the Sterling universal tool grinder. Various photographs are shown which illustrate the machine's adaptability for various classes of work. A full description of the design is also given. Another book describes their cylindrical grinders in detail.

**The Oliver Instrument Co., Adrian, Mich.**—A book devoted to their varied line of filing machines. These machines are explained fully and their capacities are stated in each case. Examples of work performed are also shown.

**The Wright Manufacturing Co., Lisbon, Ohio.**—Catalogue No. 10, dealing with their steel hoists, hand cranes and steel trolleys. The construction of these hoists is given, also specifications. Various photographs of installations are shown.

**The Quigley Furnace Specialties Co., New York.**—A little booklet dealing with their line of Q metallic alloys. The uses of their alloys are explained. Carbonizing boxes, cyanide and lead pots, tubes, retorts and sheets are shown all made from Q alloys. It is stated that these alloys can be welded, machined or fabricated as desired.

**The Ross Heater & Mfg. Co., Inc., Buffalo, N.Y.**—Catalogue F, dealing with the Ross heater. This heater is of the closed or tubular type. They are used for heating all kinds of fluids and the customary heating medium is steam. The common liquid heated is water, but oil, sugar juice, chemical compounds, or any other liquid can be heated. There are two types of heaters, instantaneous and storage. Various photographs, specifications and sectional views are given in this catalogue.

**The Hanna Engineering Works, Chicago, Ill.**—Catalogue No. 3. A very complete catalogue dealing with compression yoke riveters; 48 pages are filled with real, live information, showing details of construction, specifications and completed riveters of various types. This concern have also sent us a book of instructions that should be in the hands of anyone operating one of their riveters. It is full of practical and valuable hints that should save any trouble in operating, not to speak of obtaining maximum production. They also have a catalogue No. 10 that deals with their line of foundry moulding machines in splendid detail.

**Hardinge Bros., Inc., Chicago, Ill.**—A very complete catalogue dealing with their line of precision bench lathes and attachments. This book is filled with illustrations of all kinds of lathes and discusses the chucks used, etc., etc. Small milling machines for bench use, tool stands, saws, emery paper discs and in fact all parts for precision tools are produced by this concern. The catalogue has 116 pages and is a small encyclopedia in itself.

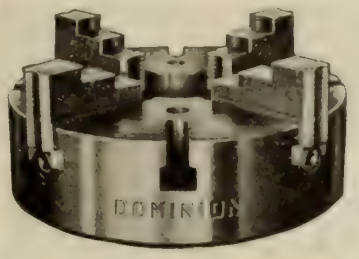
**Terrell's Equipment Co., Grand Rapids, Mich.**—A catalogue describing their line of steel cupboards, wardrobes, lockers, shelving and bench drawers. Different arrangements are shown and all dimensions of the various sections are stated.

**The Wheel Trueing Tool Co., Detroit, Mich.**—A catalogue dealing with all types of diamonds for industrial use. Holders of various natures are shown, also glaziers' tools. Diamond pointed tools are also described.

**The Electric Furnace Co., Alliance, Ohio.**—Booklet 9B, dealing with Baily electric furnaces. These furnaces are of various types and are used for melting non-ferrous metals, annealing and the general heat treatment of steels.

**The Sibley Machine Co., South Bend, Ind.**—A catalogue dealing with their various lines of drill presses. The various sizes are discussed in detail and the catalogue is well illustrated throughout.

**Internal Grinding Machine.**—Swing, 6 in. inside of water guard; 10 in. with water guard removed. Length that can be ground, 3¾ in. Diameter that can be ground, from 1¼ to 2 in. Wheel table has two traverse speeds, 34 and 78 in. per min. respectively. Workhead has three rotative speeds, 180, 325 and 590 r.p.m. respectively. The work spindle has a 13-16 in. hole clear through. The centre line of the spindle is 46 in. from the floor. Front bearing of work spindle is 1⅝ in. and the rear bearing 1⅜ in. in diameter. The countershaft which, together with one grinding head, assortment of grinding wheels, and the necessary wrenches, is included in the machine equipment, runs at 600 r.p.m. and has a pair of tight and loose pulleys 10 in. in diameter by 2¾ in. face. The pump and water tank are extra. Floor space occupied is 28 by 56 in. The net weight of the machine is 1,300 lb.; crated for domestic shipment, 1,600 lb.; and boxed for ocean shipment, 1,800 lb.



**Closed the Plant.**—The Martime Nail Works, St. John, N.B., closed on December 31st, for an indefinite period. As a result two hundred men are thrown out of employment, and the business interests of the city will be deprived of a payroll approximating $25,000 a month. Mr. Elkin, Managing Director, informed the Canadian Press that the works would be reopened when the men employed are ready to accept a wage schedule consistent with conditions in the steel market to-day.

---

**New Radiator.**—The Hamilton Tool Co., Ltd., Hamilton, Ont., have recently perfected a new radiator particularly adapted for trucks and tractors. The tubes are of seamless copper tubing held in place by a packed nut. In case of a frozen or otherwise damaged tube it is claimed this radiator can be dismantled, tube replaced and radiator mounted again in about thirty minutes' time. One motor truck manufacturer is already using this radiator on all trucks now building.

---

**In New Office.**—The Delora Smelting & Refining Co., Ltd., manufacturers of stellite tools and cutting metal, are now in the new office, 1404 C. P. R. Bldg., Toronto. In future all shipments will be made direct from Delora, Ont. Sales and service departments remaining in Toronto.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

All Screws Are Reversible

SCREWS are made of the best grade steel. Both ends are broached and are heat treated after machining. They are reversible, so that either end may be used, are large enough in diameter to stand the torsional strains applied by operator when setting up his work. They are made to give the best service—and may be depended upon to stand up under the hardest usage.

## If You Want Machine Equipment, Send Us Your Enquiries

**We have one of the largest stocks of new and used metal and woodworking machines in Canada. Many machines only very slightly used and all absolutely guaranteed. A few machines from our Toronto stock at exceptionally attractive prices are:**

**AIR COMPRESSORS**

1 3" x 1½" x 3 American Steam Pump Co., motor driven (used).
1 8" x 8" Sullivan Class "W.G. 3." Belt driven (used).
1 12" x 12" Bury Class "L." Belt driven (used).
1 8" x 8" x 10" Bury, steam driven (used).

**DRILLS**

1 10" Burke Sensitive, bench type (new).
20" "Sibley" Champions, Rockwell, and Silvers (new and used).
1 36" C.M.C. Heavy Duty (used).
1 3-spindle 20" Silver Gang Drill (used).
1 4-spindle W. & R. Sensitive (used).
A number of smaller sizes in bench and column type.

**BORING MACHINES**

1 66" Bement-Niles Vertical, 2 head, 24" under rail (used).
1 Universal No. 2½, Horizontal, table 42" x 22" (used).
1 Bullard "New Era" 36", complete equipment (new).

**GRINDERS**

1 "Landis" No. 4 Universal (used).
1- "Landis" Plain, self contained 36" x 12" (used).
1 "Norton" Plain, No. 134 (used).
1—"Fitchburg" Cylindrical, 8" x 36" (new).
Several "Globe," "Stevens," "LeBlond" and "Cincinnati" Cutter Grinders (new and used).

**SHAPERS**

1--14" "Mackenzie" B.G. Crank Shaper (used).
1 16" "Rae" B.G. Crank Shaper (used).
1 24" "MacGregor G" B.G. Crank Shaper (used).

**LATHES**

1 7" Cataract Precision (used and new).
1 12" x 8' "LeBlond" Tool Room (used).
1 16" x 6' "Reed" (used).
1 18" x 8' "Rae" Q.C.G. (new and used).
1 24" x 10' "Milwaukee" (new).
1 30" x 12' "Blaisdell" (used).

**GAP LATHES**

1 12" x 17½" x 6' Perfect (used).
1 20" x 38" x 12' C.M.C. (used).
1 21" x 30" x 7' South Bend (used).
1 22" x 40" x 16' McDougall (used).
1 38" x 54" x 12' Bertram (used).

**TURRET LATHES**

No. 1 Millhollands, capacity 1⅛" (used).
Several Oliver & Davis Turrets, various capacities (used).

**PLANERS**

1 42" x 42" x 20' Putnam, 1 head (used).
1 30' x 30" x 10' Pond, 1 head (used).
1 24" x 24" x 6' Powell, 1 head (new).

**MILLING MACHINES**

1 Whitney Hand Miller, 18" x 6" table (used).
1 Briggs High Duty Type "A," 22" Traverse (new).
1 Briggs High Duty Type "B," 42" Traverse (new).

**POWER HACK SAWS**

1 No. 10 Racine 8" x 8" cap. (new).
1 Peerless 6" x 6" cap. (used).
1 No. 7 Watkins 9" cap. 18" blade (used).

**MISCELLANEOUS**

1 Arbor Press No. 4 "Greenard" (new).
1 Riveting Machine No. 80-B, "Grant" (new).
1—Riveting Machine No. 81-A, "Grant" (used).
1 High Speed Hammer No. 3-A (used).
1 Rotary Bevel Shear, "Lennox," 1" cap. (new).

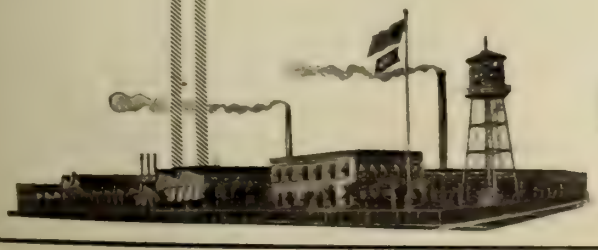
# MILWAUKEE MILLING MACHINES



## Milling Satisfaction Assured

A LARGE variety of engine parts are milled in the plant of the Fuller & Johnson Mfg. Co., Madison, Wisconsin. Milwaukee Milling Machines are doing this wide circle of work with ease and rapidity. Closest limits of accuracy are maintained by these machines.

The massive one-piece box section column —the box section knee with solid top and extended slide—the saddle and table of ample proportions and wide bearing surfaces, and the patented double overarm afford a degree of rigidity to Milwaukee Milling Machines that assures accuracy and production on all milling jobs—light or heavy.

These reliable outstanding features, together with actual results obtained, are responsible for the selection of Milwaukee Milling Machines to solve the milling problems of manufacturers in whose plants speed and accuracy are essential, either separately or in combination. They know the "Milwaukee" gives complete satisfaction.

# Money Saving Information

"The most useful information contained in any paper I get"—so a Western banker writes in to-day's mail, renewing his subscription for FINANCIAL POST.

"Very often," his letter goes on to say, "I am called on to suggest investments for small amounts, sometimes as low as a few hundreds, and I find your Investors' Inquiry Service a reliable partner to consult. If every investor knew there was such a service at his call it would surely lessen the losses of many of these people."

The Investors' Inquiry Service fills just that need. Unless you are perfectly sure of your investments, write us before you buy.

It costs FINANCIAL POST subscribers nothing to be sure before placing hard-earned savings in stocks that may never have a chance of paying dividends.

Trained service men will give you the benefit of keen analysis based on the facts behind the securities you are considering. This is one of many features enjoyed by our readers.

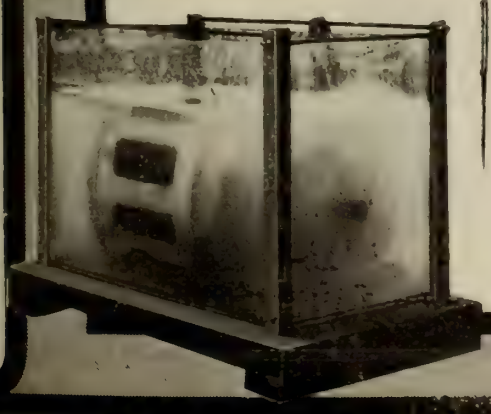
# LINCOLN ARC WELDER

## *If You Make Iron and Steel Products*

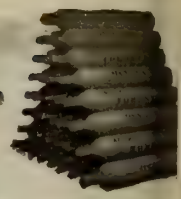


sooner or later you will become interested in a Lincoln Welder.

You will want to know all about it—what it will accomplish, and what it will save. You will want a Lincoln engineer to conduct an investigation in your establishment. You will permit him to make experimental welds.

As we have said, you will eventually decide that a Lincoln Electric Welder in your shop would, without a doubt, save time and money.

Why not get these particulars now, and thus begin to make the saving from the commencement of the New Year?



*"Link up with Lincoln" for Performance and Service*

# OXYGEN AND HYDROGEN
## (ELECTROLYTIC)

National Electro Products Limited is the largest manufacturer of Electrolytic (pure) Oxygen and Hydrogen in Canada.

WE PRODUCE GASES EXCLUSIVELY BY ELECTROLYTIC DECOMPOSITION OF WATER

We are, therefore, in a position to furnish Oxygen and Hydrogen far superior to like gases made by any other process.

After Exhaustive Tests We Have Decided to Handle the Well-Known

The Torch for Welders PUROX Who Want the Best!

## WELDING AND CUTTING TORCHES

Our entire organization—technical and sales—is always at your service.

# For Repairing Broken Machinery or Tools of Medium Size

TURNER Oxy-Acetylene WELDING & CUTTING Equipment

These outfits will soon pay their cost in machine parts or tools reclaimed. The sectional extensions of the torch enable the operator to adjust it to any desired length or angle. The location of valves is such that the flame is controlled by one hand, leaving the other hand free for the work at all times.

For full particulars write

# IMPERIAL CARBIDE

For Welding Cutting and Lighting

HIGHEST GAS YIELD IMPERIAL CARBIDE MADE IN CANADA

It insures **effectiveness** and **economy** by **invariably** producing acetylene gas of **unusual purity.**

Manufactured by

**Union Carbide Co. of Canada, Ltd.**
WELLAND, ONTARIO

**Large Stocks maintained at convenient distributing centres throughout Canada**

# DOMINION OXYGEN
## —*Growing with Canada*

THE Dominion Oxygen Company, Limited, is contributing a commodity and a service to Canadian industry. The Commodity is the highest grade of commercially pure oxygen. The Service is a growing chain of distributing stations that makes Dominion Oxygen always available in the quantity needed.

The first four distributing stations already in operation are the result of the Dominion Oxygen Company's first year of expansion. They are the measure of the success of the Company's efforts to give immediate and unfailing co-operation to gas users.

By placing within easy reach of every manufacturer in Canada an unlimited supply of the oxygen he needs for production and repair work—

By filling all orders for oxygen on the day they are received—

By using a cylinder light enough to make handling more economical, yet large enough to hold 220 feet of gas, and strong enough to pass the rigid requirements of the Railway Commission, and—

By adopting a liberal cylinder loan policy,

The Dominion Oxygen Company, Limited, feels that it is aiding materially in Canadian industrial expansion, and is justifying its program of additional plants and warehouses.

ALL STEEL

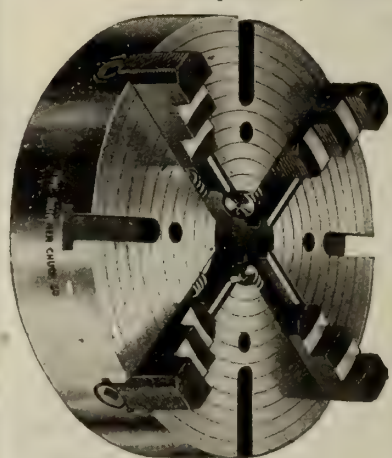
## INDEPENDENT CHUCKS

are not an experiment—they have come to stay. They are a necessity with the modern machinery and high-speed steel cutting tools.

THE UNION STEEL BODY CHUCKS

are well designed and have all the elements of strength and durability for which they are designed. We make other types in steel also, including the Geared Scroll Chucks and the Geared Scroll Combination—all designed for heavy work and hard usage.

**UNION MANUFACTURING COMPANY**



New Britain, Conn.

*New York Office:* 26 Cortlandt Street

*Makers of a complete line of chucks*

## Strong Chucks—

That truly describes Skinner Steel Body Independent Lathe Chucks. They are not only strong and powerful, but wonderfully accurate. The

4-Jaw Independent Chuck, Steel Body, for Heavy Duty

**SKINNER Steel Body Independent Lathe Chuck**

is a single steel casting of great strength, well proportioned and accurately finished. Face is graduated accurately in inches. Screws and bearings are made of the toughest steel to withstand abnormally hard wear.

The dependability of Skinner Steel Body Independent Lathe Chucks is conclusively proved by the fact that not one has ever been known to break in service—and we have been making them for many years.

*Write for catalogue and illustrated literature.*

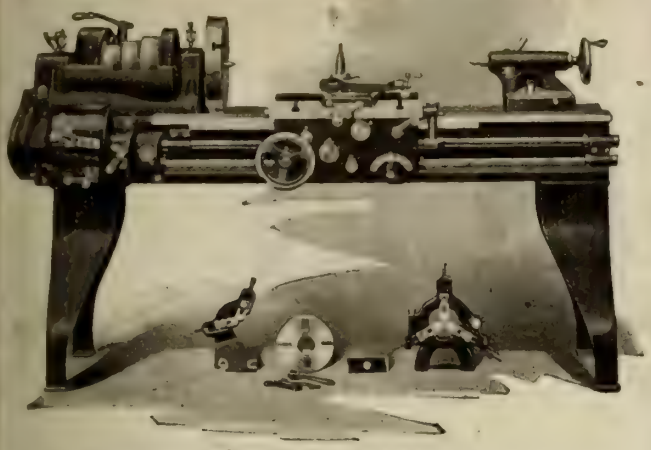
# METALLURGISTS

***The following advantages are secured by the Continuous Method of Heat-Treatment:***

Bringing material up gradually to the final temperature.
Utilizing heat in spent gases to preheat material.
Exposing each piece to heat in same manner, to same temperature, for same length of time.
Uniformity not only of the individual piece but of the sections thereof as compared with the corresponding sections of other pieces.

**DO THESE ADVANTAGES APPEAL TO YOU?**



***Write for Bulletin 217-T and learn whether the continuous method is adaptable to your product and manufacturing conditions.***

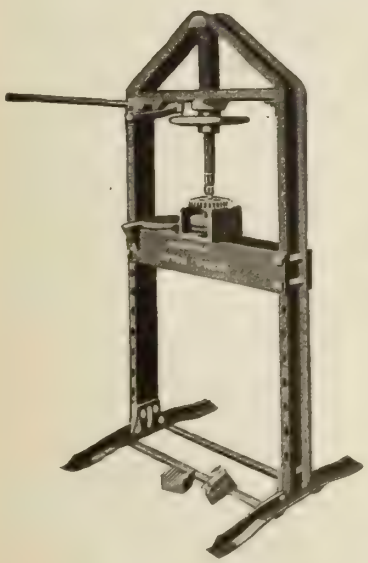
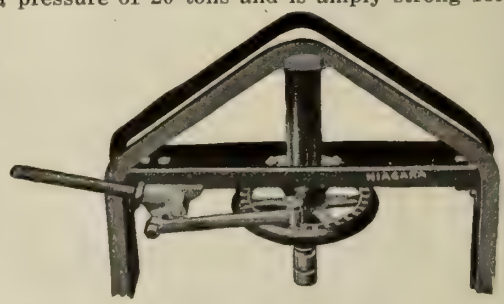
**INDUSTRIAL FURNACES**



Most modern, efficient and economical heating method. Made in Canada! Full details on request.

General Combustion Co. of Canada, Limited
619-623 New Birks Building, Montreal

You'll Save Time by Using a

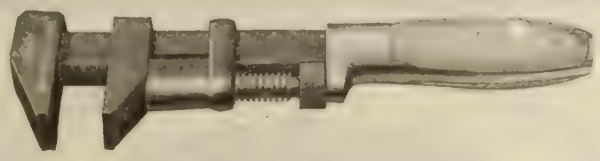


**NIAGARA PRESS**

An All-Steel Press With a Leverage of 1500 to 1

ONE reverse stroke of the lever—that's all you need—and the mighty pressure exerted by this strong, light weight press is immediately released. Ordinary presses require from 15 to 20 strokes. Think of the time saved by using a Niagara.

The Niagara forcing press will exert a pressure of 20 tons and is amply strong for the work it is designed to perform. It can be operated with little effort by one man. It has a multitude of uses in every garage and machine shop for removing hubs, bearings, straightening axles, shafts, etc.



Also manufacturers of other automobile accessories such as engine frame stands, auto twin jacks, light and heavy car type and auto jacks. Sundry accessories. Heavy accessories a specialty.

Write for full particulars.

*Made in Canada by Canadian Workmen*

The L. & P. MANUFACTURING CO., LIMITED
NIAGARA FALLS, ONT.

**Where strength and dependability are requisite specify Williams' "W & B" Machinists' Knife Handle Wrenches. Fitted with easy-acting screw. At your dealers. Write for catalog.**

## J. H. WILLIAMS & CO., Limited

# HENDEY

## Real Satisfaction on Precision Work

The Bates Valve Bag Company installed their Hendey Shaper some eight years ago. Since that time they have purchased another Hendey Shaper, and a Hendey Lathe.

This company produces special machinery for filling cement bags. The work here shown is a die block for a wire bag tying machine and the limit of accuracy demanded is .001".

The Bates Valve Bag Company say that for real satisfaction on precision work there's nothing to equal Hendeys.

# *Does It Pay to Order Just* "HACK SAW BLADES?"

Many hack saw users grow careless. They order just "hack saw blades."

Because it has been the standard blade for 35 years, most dealers will fill this order by sending you Star Saws, but —

It doesn't pay to take the chance. You might get fooled some day by receiving an inferior saw blade. It's much safer to specify "Star," every time.

The poorer blade will mean a loss, both in time and material that will amount to much more than the difference in price between Star and ordinary blades.

Slow cutting blades waste valuable time not only in cutting but in frequent changing. They run up your production costs and cut down your profits more than many manufacturers realize.

Ordinary blades have the old "wood saw" tooth and two-way clearance. Star blades have an undercut tooth and three-way clearance that are made for cutting the hardest metal and do a variety of work that is impossible with ordinary blades.

Star saws prove their better quality very quickly in two ways — they will go through metal that other blades refuse to cut. And one Star blade will cut a far wider variety of sizes, shapes and metals than is possible with ordinary saws.

Make these two tests yourself with Star saws and you will never be satisfied to have other blades used in your shop. Our service men will be glad to help you solve your production problems on Hack Saws if you will write us.

**STAR SAWS NOW SOLD BY THE MAKERS**

We now sell our own product for we believe no other organization is in such a good position to give selling service on Star Saws as our own factory that has made them for 37 years.

We are not satisfied only to sell you Star Blades but stand ready to render you every service in getting the best results in their use.

"Good workmen know the difference"

# *Not bolted to the floor—why?*

*(Ask Gordon Scott, He Knows)*

This was in August, 1919.

Gordon Scott, Manager of the Peerless Surfacing Machine Company of Troy, New York (manufacturers of Peerless Surfacing Machines), laid down the report of the tests. "It's as if we had built a fine safety razor but couldn't get good blades for it," he said.

These tests showed that Peerless Surfacing Machines were O. K., true-running, production boosters —that the defective work complained of was due to the abrasive belts used.

"Ordinary belts won't do," ran the report. "Their belt joints are thicker than the rest of the belt and give a marked 'hop' or 'jump' on each revolution. This causes marred, scratched work."

And a little further down Scott read, "One belt stands out—Speed-grits Uniflow belt. Recently developed by Manning Abrasive Company. Has an absolutely flat joint. No 'jump' or 'hop' no matter how many R. P. M. Gives perfect finish."

Now notice the picture above. A Peerless Surfacing Machine running at top speed while simply set on the floor (*not* bolted). Its "jumpless" Speed-grits Uniflow belt is grinding a block of carbon steel.

On steel, alloy, iron, wood, or hard rubber—smooth-running Speed-grits Uniflow belts give speed in production *plus* perfect finish.

Today you can order Speed-grits Uniflow belts by mail—one or a dozen. Just send a piece of a wornout belt of the type now being used.

(Many abrasive-belt users tell us that taking the "jump" out of the belt joint is the biggest thing accomplished in the abrasive industry since the discovery of artificial abrasives.)

Why not find out? Order your trial Uniflow belts today.

*"Good Workmen Know the Difference."*

Send for "The Difference Book." Address

# Do you choose a hack saw for appearance-or performance?

Hacksaws all look about alike. Weight, teeth, thickness and finish seem to be similar. The difference is in their performance.

No matter how good the saw may be it's certain that the blade made to cut soft metal won't cut cold rolled stock. There's no such thing as a hacksaw capable of cutting all materials equally well. Fact is, there's only one way to be sure of the right blade and that's by the hacksaw chart.

Picking the right blade for the particular kind or shape of metal is easy if you use Starrett saws according to the Starrett Hacksaw Chart.

We will be pleased to mail you a copy of the chart. Free. Also ask for Catalog No. 22 "3".

## You Can't Afford to Get Along Without Compressed Air

Its uses throughout the plant from foundry to paint shop and shipping floor are so numerous and so extensive that the question is not whether to use air, but rather, where else can we use compressed air?

Canadian Ingersoll-Rand Compressors, Air Hoists and Little David Pneumatic Tools play a large and important part in such calculations, for to them is due the credit of making the pneumatic way of doing things a bit less expensive.

*Our nearest sales office will gladly advise you regarding new equipment or show you how to get more and better service from what you have*

# No. 2 TYPE "R" Hartness Automatic Die

*WITH SHANK FOR REVOLVING SPINDLES*

These dies are designed for use on either vertical or horizontal spindles. Die is re-locked by forward motion of sleeve, which may be actuated by a yoke working in the groove or by a fixed stop making contact with rear edge of sleeve at the return stroke. Die is unlocked in the usual manner by retarding its forward motion or by a fixed stop, making contact with the external tripping button shown on the face of the die. External tripping button is especially desirable in cutting very short threads as it relieves the thread of the strain incidental to unlocking by the pull-off device

**The diameter of the No. 2, Type R die is 3 3-16 in., and its length as shown is 3½ in.**

**The Die cuts both right and left-hand threads ½ in. to 1 in. in diameter, and from 10 to 40 threads per inch.**

**Shanks are varied to meet individual requirements.**

**A set of standard chasers in carbon steel is supplied gratis with each Die.**

**No tools of any kind need be used in changing chasers.**

**A chaser grinding jig is supplied gratis on Die orders if desired.**

# THE JOHNSON FRICTION CLUTCH

## IF YOU BUILD MACHINERY

you are anxious to put into your product every refinement which will add to its efficiency—which will make it serve your customer longer and more satisfactorily.

One of the most important features of any machine is its clutches. No single item adds more to machine performance than a good clutch, and nothing can be a greater source of annoyance than a poor one.

Play safe and equip with Johnson Clutches.

*Write for Our Yellow Catalog and Booklet "Clutches as Applied to Machine Building"*

## IF YOU USE MACHINERY

you are looking for the machine with the highest rate of production, the smallest amount of lost time, and the longest life. In all probability you will find that machine equipped with a Johnson Clutch, for the Johnson Clutch not only gives best service, but adds greatly to the convenience and speed of operation.

Look for it on the machine you buy, and to be consistent equip your plant transmission in the same way.

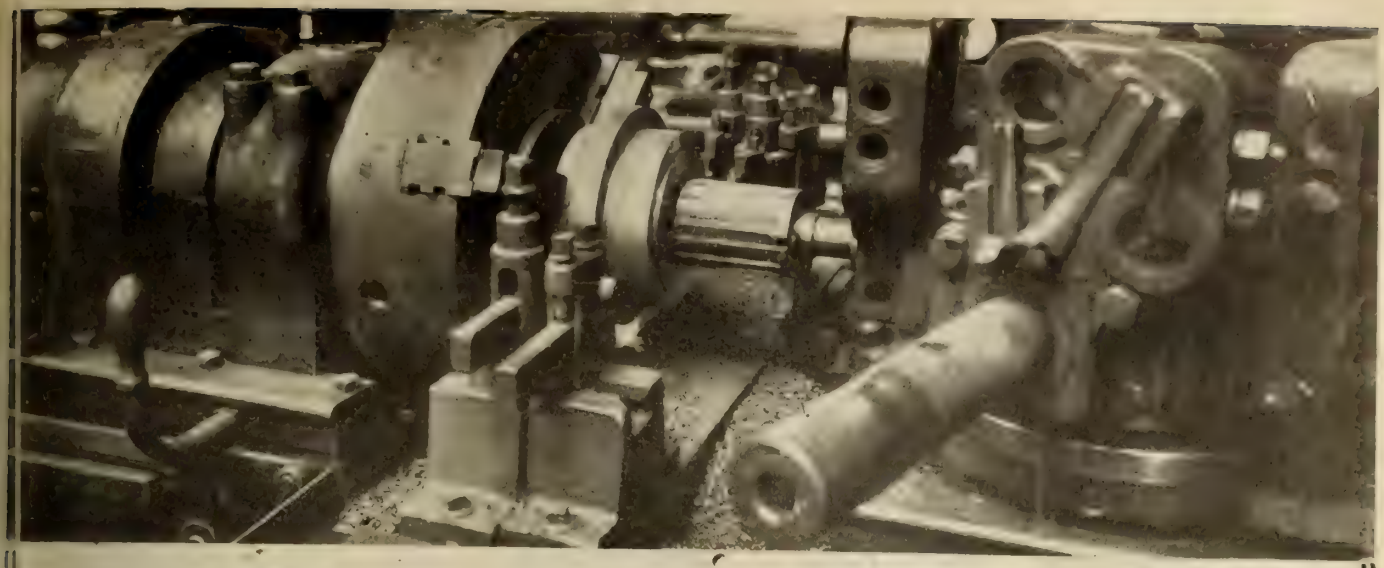
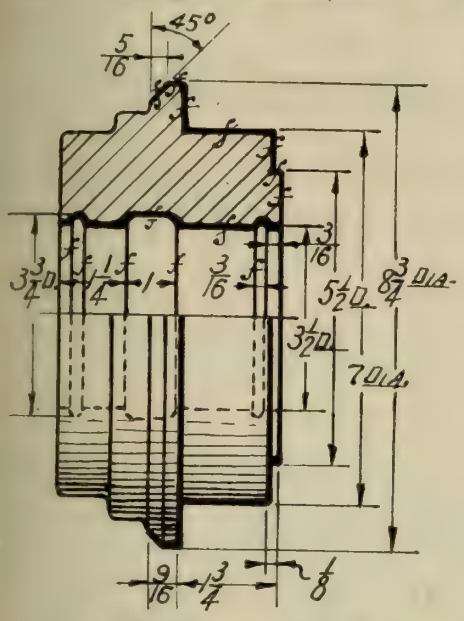
# Cab Tire Cable



A flexible, wear-resisting cable especially designed for industrial use. The several conductors are individually insulated with rubber and further protected by a heavy outer jacket of smooth, tough, and flexible rubber.



Like its namesake, the Cab Tire, it is manufactured to stand rough usage and to give service under the most trying conditions.

Railways, Shipbuilding Companies, and Industrial Works are amongst the largest users. It fills a long-felt want for a suitable flexible for portable lights on ships. Railways find it the ideal cable for motor-driven tools in shops and round-houses, while in Chemical Works the absence of braid covering has made it particularly desirable.

# The City of ST. JOHNS, QUEBEC

## Offers To Manufacturers—

### *A Cash Bonus On Your Payroll, Exemption From Taxes, Etc.*

Already a busy industrial centre, St. Johns is rapidly expanding and now offers unparalleled inducements to encourage the establishment of new industries.

Every new industry is exempt from taxation for a period of fifteen years, such period being subject to extension. A bonus of 5 per cent. will be paid on your payroll for a period of five years. If you desire it, the city will advance this to you to be applied to the purchase or erection of any building suitable to your purpose. All public improvements you may require, such as street extensions, sidewalks, waterworks and sewage will be attended to by the city.

In addition to these inducements, St. Johns enjoys one of the finest industrial locations in Canada; has unequalled transportation facilities, an adequate fuel, power and labour supply, making it an unusual industrial opportunity.

## No Other City Can Offer These Combined Advantages

Seven railroads, including Canada's great transcontinental lines.

Finest ocean shipping facilities.

Canal connections with New York, the Eastern States and the Great Lakes.

Cheapest labour market in Canada.

Plentiful supply of skilled and unskilled labour.

Cheap and abundant electric power.

Cheap coal and lower freight rates.

Desirable factory sites with all public conveniences immediately available.

Extraordinary inducements to new industries.

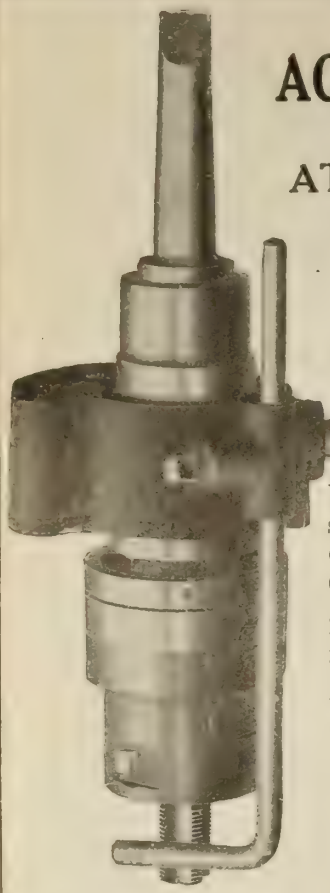
# A Problem In Every Spring

BECAUSE a spring is more than a twisted wire, it is only rarely that the experience of the manufacturer enables him to properly design the springs which go into his product. If you can we will follow your specifications to the letter.

Otherwise, better depend upon us for this service as hundreds of manufacturers do. For our 63 years of spring-making experience, added to our sound engineering practice, enables us to fill your requirements in a practical way. Only the other day our Engineering Department re-designed a client's spring so that it can be produced for half the cost. And we supply exactly the springs you need - daily, weekly or monthly.

Let us put this ability at your service on your product -new or old.

## THE WALLACE BARNES COMPANY



*"Spring Makers for Three Generations"*

Main Office and Works: Bristol, Conn.
Western Sales Office; Book Bldg., Detroit

Springs of steel, brass, phosphor bronze or vanadium—flat, coiled, spiral—compression, extension or torsion. Wire Forming, Spring Washers, Small Parts of steel, brass, etc., in any finish. Assemblies. High Carbon Cold-Rolled Steel.

*If interested tear out this page and place with letters to be answered.*

THE
ACKWORTHIE
TAPPING
ATTACHMENT.

BRITAIN'S PREMIER CHUCK

Made in 6 sizes.
To tap from ¼ in. to 1¼ in. Whit.

We have made some thousands of these Chucks during the last 11 years, every one of which has given satisfaction. For tapping holes there is nothing to equal them for speed and handiness.

*Shall we mail you particulars?*

BIRMINGHAM

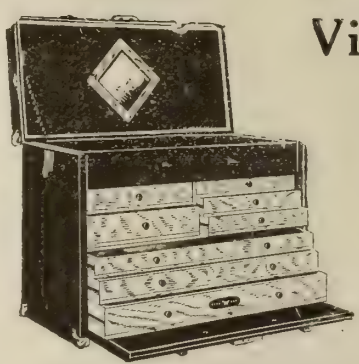
DUNBAR SPRINGS

ACCURACY ASSURED

You can always depend upon Dunbar Springs being accurate. Before proceeding with any order the first few springs are carefully tested and checked up for this very purpose.

Seventy-two years' experience making flat and spiral springs of every description enables us to furnish you with springs of the highest quality, that can be depended upon under all conditions.

Send blue prints for estimates.



The Dunbar Brothers Co.
BRISTOL, CONN.

# Machine Shop and Construction Supplies

The Rice Lewis line includes Pipe Vises and Pipe Wrenches, Micrometers, Torches, Set Screws, Cap Screws, Machine Screws, High-Speed and Carbon Drills, Files and Machinists' Tools of every description.

We also carry large stocks of Bar Iron, Sheet Iron (black and galvanized), Machine Steel, Cast Steel, High-Speed Steel, Cold-Rolled Steel.

## Victor Hack Saw Blades

Durable, fast cutting blades which cut true on the toughest metals. Users find that Victor Blades cut faster and last longer than ordinary ones.

## CRESCENT
BELT FASTENERS

Maintain a uniform grip, the entire width of the belt. They clinch beneath the surface on the pulley side—no part in contact with the pulley.

### Machinists' Tool Chests

All Rice Lewis goods are quality products—made to give the greatest service for your money. Ask for quotations as to prices and dates of delivery.

# *Necessity's Understudy*

USERS deserve equal credit with our Service Engineers for the constant development of new uses for Boyer Riveting Hammers and Little Giant Air and Electric Drills.

In one, two, three order, three typical uses developed through their close co-operation are—

A Boyer Riveting Hammer driving drift bolts with *one* man on a two-man job. This is proof of two things: labor-saving adaptability of the tool and ingenuity in applying it, both made possible by the *powerful* Boyer stroke.

A Little Giant Portable Electric Track Drill drilling truck chassis. Supplies its own "old man," and works *six* times as fast as the portable drill it replaced, with one man less.

A Little Giant Portable Electric Drill mounted on a buggy. Almost as fast as this man can raise and lower the buggy handles, this Little Giant countersinks—an average of *9½ holes a minute.* Think of it!

Conclusion: If Necessity is the Mother of Invention, C-P Engineers are her Understudy, working first-hand with users and constantly widening the already wide utility of C-P labor-saving tools. Ask for bulletins.

# Your Grinding Problems are OURS

## Send Prints of Your Work —We will Furnish Data

### Small Short Work

The hole in this hardened gear is .237 dia. x ¾" long. There was .005 to remove to a limit of .0005 and a new operator turned off 50 per hour the first week. An ideal machine for work ¼ to 2" diameter x 2½" long.

***How is your production on small holes?***

Heald Style 85 Hand Feed Internal Grinder

### Hole and Face Grinding Differential Gears

Style No. 75 was equipped with a cross slide work head. The adjustment on this work head allows for quick horizontal movement when the head was drawn from the hole to grind the face. The stock on the holes ran from .020 to .030 and were ⅜" wide, finishing 6½" in diameter. The face needed about .010 to clean and was ⅞" wide. The tolerance was plus .002 and Heald turned them off at one minute fifty seconds each.

***There are hundreds of internal grinding problems. Let us solve yours.***

Heald Style No. 75 Hand Feed Internal Grinder.

### Production—Finish—Accuracy

These steel gears were ground at the rate of 400 per hour on a Heald Style No. 22, removing .005 to .010 stock to a limit of .001.

**Let us prove it will be equally fast on your work. Send us 100 samples for production figures, wheels, methods of holding, speeds, limits, etc.**

# The Problem of Producing a Geneva Gear

## A Tale That Will Make You Smile. It's a Mixture of Invention and Mechanics, and Brings Into Play a Scotsman, a One-legged Man, a Hebrew, Yes—and Even a Minister.

By DONALD A. HAMPSON

IN our October 26th issue we published an article dealing with the problem of machining the Geneva motion shown at Fig. 1. This problem has evidently got our readers thinking and here is how one of them would machine the piece.

The question of the Geneva gear is one that I had to answer for myself on just the same kind of a job five or six years ago. The gear for that particular purpose brings to mind a series of events such as everyone experiences when taking in model and experimental work. Your clients appear out of the thin air —their proposition or idea is as different from the previous one brought in as day is from night—you run the risk of losing some money before you get through with them, but you add **immensely** to your experience, chiefly along the line of your changed view of human nature.

When Sandy Moritz came in and wanted to hire the use of a lathe, we refused him. We always do so, and besides this gentleman was a total stranger to us. Later, he brought in several cylindrical grinding jobs which he insisted on seeing done (and even assisted in doing, when the foreman wasn't looking). All these little things, however, were laid to his Hebrew nature.

Some months later, a one-legged stranger appeared and wanted to speak to me confidentially. I told him to "shoot" right where he was, for I was able to keep any secrets he wished to disclose, but I would not entertain any proposition that was shady. Well, in a soft, cultivated voice he told me that he wished to get some work done on a mechanism that had to be guarded very jealously from outsiders who might steal the idea. He also told me that he was a retired minister, that in his work as a lecturer he had noted the ripe field for this device, which when perfected would make him independent, and the manufacturer whom they selected secure against any lack of work. I had heard of that kind of bunk before, though I was too polite to say so.

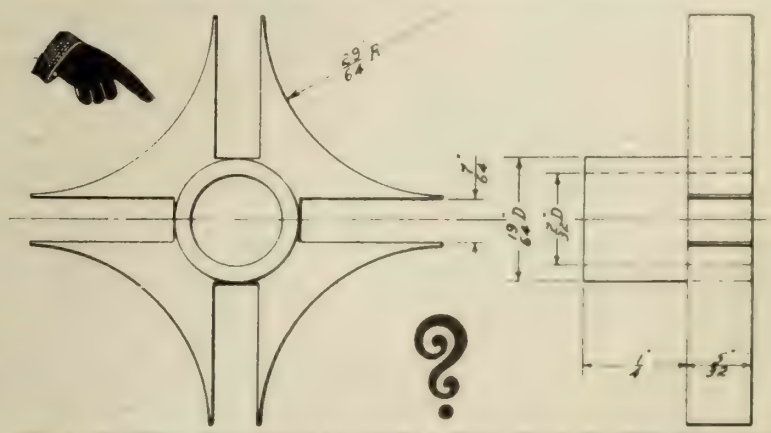
Another lapse of a month and my ministerial friend reappeared, bringing a brother minister, Dr. Morse of a local church, and his son, an insurance agent, an echo or repeater of everything the elder Morse said. They had a small package between them which the doctor, in his most unctuous voice, told me contained their machine which they would show me in private. Said machine, on being exposed, was found to be the half-finished model of a moving picture projecting machine, but the model so far had included nothing more than the film moving parts. It was explained that this machine was so much simpler and lighter than the Pathescope and other commercial types, and the films could be handled so much more readily that it would find instant sale among churches, lecturers, and societies who could not afford to buy the expensive machines that required a skilled operator.

I noted that the machine was "open side," a light plate of cast iron into which the roller and gear studs were set. This was one of the features making for easy loading. There was also an absence of toothed feeding wheels for the film. The scheme was to feed by passing the film between two friction rollers, one of which was driven by a curious looking Geneva gear. This Geneva was a "special design of their Mr. Moritz" and was to give the film a faster speed with the same dwell. I dropped the remark that I had seen an improved design of just such a gear in a recent number of a trade paper, but my friends said I must be mistaken because Mr. Moritz had originated this Geneva himself, working on it for the past eight months.

It seemed that Mr. Moritz was their engineer, engaged for the purpose of developing the picture machine, though when this was afterwards mentioned to him alone, he claimed to be an equal partner in the enterprise through his having conceived the whole thing, the others simply putting up the money. My ministerial visitors explained that they were tired of fooling along with Sandy. Frankly, they thought he was stringing the job along as a means of earning a soft living—and they wanted our place to finish the machine in a first-class manner.

If Moritz came along and wanted work done that we deemed advisable, we were to do it, but otherwise to follow instructions, and our best judgment.

A little thought applied to the design proved that it was too light for the scheme, with its feed rollers supported on studs and depending on the grip of the rollers to apply a positive movement



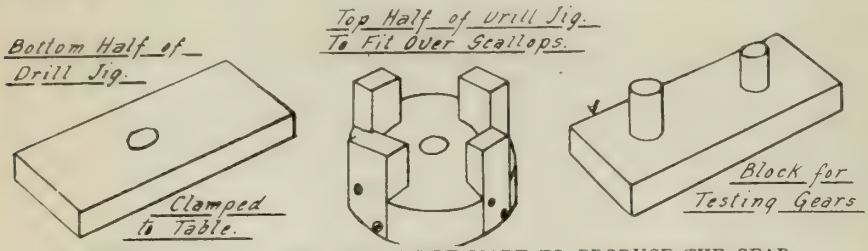


FIG. 1 SHOWING THE ORIGINAL GENEVA GEAR THAT STARTED THE TALK

to the film. We were forced to tell the trio this, but evidently they considered themselves better qualified on this point, for our objections were overruled, so we went ahead with the work. It turned out to be one of those jobs where there are loose fits and improper materials and inadequate design, where you re-make and tinker and patch, only to have a piece of junk on your hands in the end. But anyway, we made a number of demonstrations, each of which proved that the whole thing would have to be constructed along different lines if it were ever to be a success. The friction feed, the open side, and the hand-made Geneva all failed miserably. Even the clerical gentlemen could see this.

HERE ARE THE PARTS THAT WERE MADE TO PRODUCE THE GEAR.

### The Task of Re-designing

In the end, we were allowed to re-design the machine on a more practical basis. One of the men made a perspective of the proposed machine so our customers could "see" how it would actually appear. This pleased so much that we were commissioned to go ahead with some of the parts for a hundred machines, among the parts being the Geneva gears, and some pins of odd size drill rod. That drill rod is around yet. The driven member of the Geneva pair was slightly larger than the one illustrated in Canadian Machinery.

We had no trouble in producing smooth, close working parts for this purpose. We cut pieces of machinery steel five inches long, centered them carefully, turned all the shoulders or necks and turned the flange parts to the outside diameter of the points. Then we milled the slots and rough milled the scallops; the slots are the least important part of the gear and a slight inaccuracy only results in an interference with the driving roller, easily remedied by filing the mouth of the slot. Finally, with a sharp cutter and a fine feed, the half-rounds were finished to size, paying careful attention to the condition of the centers of the piece being milled.

The shaft hole in the gear was made in a drill press. A simple jig located the hole concentric with the half-rounds, with the blank lying in a cast-iron block on the table of a sensitive drill press. We concluded that this would be a more satisfactory and accurate method of making the holes in single or double blanks and cutting the latter on arbors—and we were very well satisfied with our method.

For the milling, we bought a special radius cutter from one of the well-known manufacturers of such tools. Our method of trying the work was to micrometer the pieces during the milling operation and to test the two members of a pair on a simple two-stud fixture such as is used for spur gear running tests. The operations throughout were simple, as we had planned, and we rejected but a small percentage of the pieces. We tried turning the parts out of square stock to save some milling but we found that the damage to center holes in turning affected the accuracy of the milling, so we stuck to round stock with its even cut in the lathe.

Our experience with moving picture machines might have been greatly broadened from that time if we hadn't in some way offended the promoters. It came about through Moritz's borrowing the original machine, presumably to take to their own little workshop for experimental tests. We hadn't been told not to let him have the run of things and so we let the machine go, but we had a suspicion that Sandy was trying to make a getaway and we took the trouble to phone Dr. Morse, who swore under his breath and made a bee-line for the railroad station, catching Sandy just in time. Following that episode, the former made for our place and gave us a most wonderful dressing down, polished and embellished by years of hell-fire ranting in the pulpit. We laughed.

A few days later on some pretext, they took the Geneva gears away. They already had the design of the new machine in their possession. Still later, the one-legged dominie showed up and asked for the focusing lens that we had, said lens having been brought around for measuring purposes—our design of machine having included this unit, the shutter, tripod, lights, and tilting arrangements. As we had had the lens only an hour or two, this demand struck us as funny—not so the good man, who raved most unbecomingly and muttered threats of police as he went off. Our pay? We got part of it, but the trio insisted that they should not pay for the "poor work' upon the original machine—and they didn't. We had no redress, because you can't collect much from a one-legged dominie, a minister of a city church, an insurance agent, and a Jew, all of whom are out to get rich without working—so when this combination appears in your machine shop with an invention to be developed, either insist on a drawing account at the bank or plead more work than you can handle. Dr. Morse has given up the pulpit and neighbors of the one-legged man say they are now on easy street. Sandy has permanently disappeared, from which we conclude that we gave them a fair start in business after all.

## CAUSES OF CORROSION

"To my mind," said Dr. O. F. Hudson, of the Admiralty research laboratory, at a recent meeting of the Society of Chemical Industry, in Birmingham, "electrochemical is not the sole cause of corrosion in the case of copper and brass, and that in most cases, in neutral or slightly alkaline solutions, that action was relatively unimportant, the greater part of corrosive attack in these cases being due to direct chemical action. In acid liquids, and industrial waters which had a distinctly acid reaction, electrochemical action might play a more important part, but in such cases the metal e.g., condenser tubes, failed by general thinning rather than by pitting or localized attack, which was in other cases generally the chief trouble. Electrolytic protection processes probably owed their efficiency largely to the production and maintenance of a uniform resistant scale of calcium carbonate. There was little hope of finding an alloy which would resist corrosion under all conditions.

## DRILLING IRREGULAR SHAPED HOLES

The accuracy which has been attained in the drilling of square holes has led inventors to proceed still further. It is now claimed that a Hungarian named Bartholomius has a machine that is said to be free from the defects of earlier types, and is automatic in its action.

It can be attached to any boring machine, lathe, etc., without regard to the type or method of supporting of the particular machine. The device is, in fact, an independent and self-contained tool. The angular holes are drilled very accurately, as the drill is guided over the whole of its length, and the work-piece and the clamping device are in immediate contact with the guides. At the same time that round holes are being drilled, the new type of boring tool automatically drills hexagonal and polygonal holes. To obtain different sized holes it is only necessary to change the drill used. From the description we imagine it to be somewhat similar to those at present on our own market.

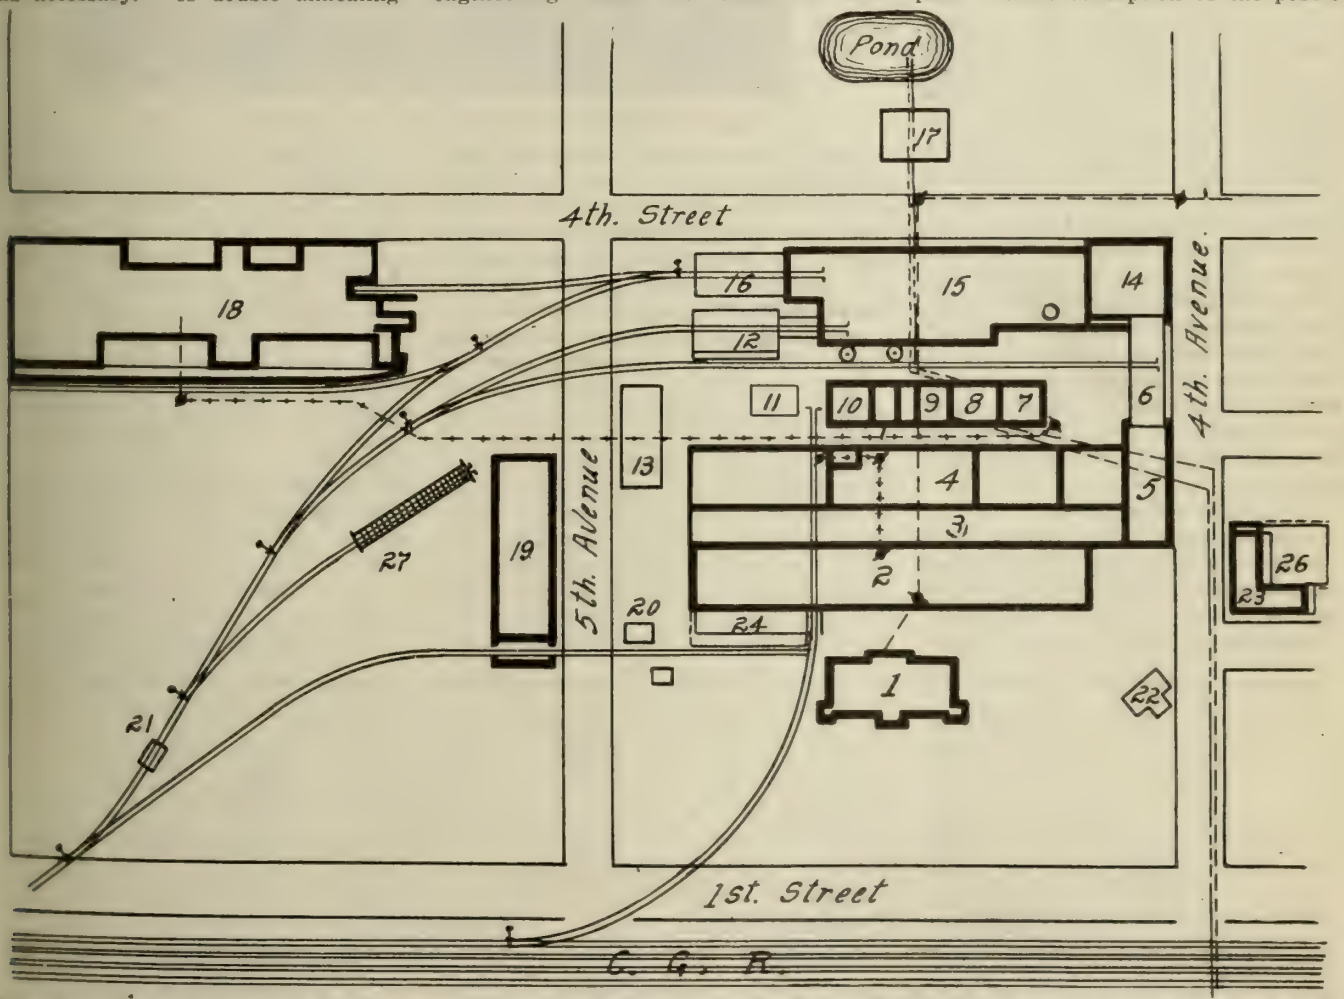
## WELDING SOCIETY

The next meeting of the Canadian Welding Society will be held on Wednesday evening, January 26th, 1921, at p.m., in the offices of L'Air Liquide Society, Suite No. 451, Confederation Life Building, Toronto. The entrance to this building is at 12 Richmond St. East and all interested are requested to be on hand.

# An Interesting Industrial Plant in Quebec

By J. H. RODGERS

THE new plant of the National Farming Machinery, Ltd., Montmagny, Quebec, contains many features of interest. This plant is engaged in the manufacture of all kinds of agricultural machinery and farming implements. A big feature in connection with this plant is the fact that not only will they make the implements, but they will produce the material used for the same, as far as possible.



With this idea in mind they have installed a complete modern rolling mill for the necessary steel bars and shapes used in their plant.

A general plan of the entire works is shown, this view illustrates the layout of the property and the different buildings. At the rear is the foundry, 342 feet long by 115 feet wide, containing two basic open hearth steel furnaces, each one capable of producing 1,500 tons of steel per month. Foundations are also laid for a third furnace if found necessary. A double annealing oven, 20 x 10 x 10 feet, oil fired, is located alongside the furnaces to provide for the annealing of large castings. In this foundry all the steel rolls required for the mills will be cast. In addition to the steel furnaces there is a one-ton Bessemer converter, and two 5-ton grey iron cupolas. An extension is being provided, approximately 100 x 100 feet, to increase the moulding floor capacity of the cast iron section. Three overhead travelling cranes, one 50-ton and two 25-ton capacity operate in this department. The foundry is fully equipped with moulding machines, and all the latest and modern appliances for rapid and efficient production.

### Administration Building

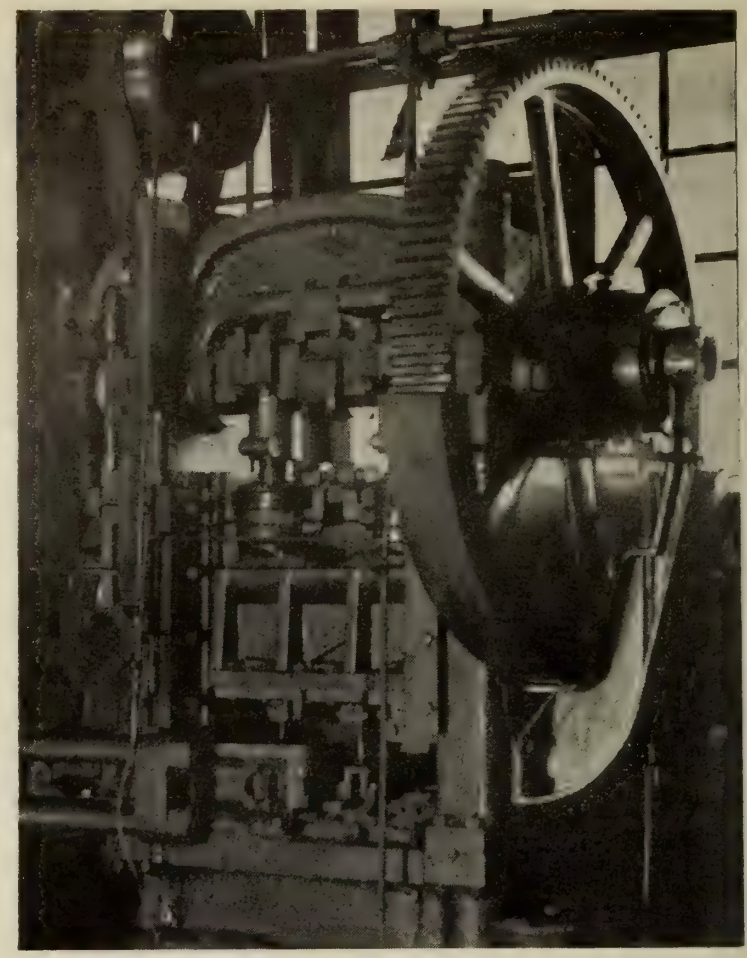
The administration building is a two-storey brick and concrete structure, situated at the front of the property and facing the main line of the Canadian National Railways. All executive and engineering offices are located in this building, and likewise adequate show rooms for the wide variety of product manufactured and sold by this company. Immediately in the rear of the general offices is the machine shop and gas engine department. This building, constructed of brick and reinforced concrete, has a total length of 450 feet and a width of 110 feet, the center portion for the complete length being designed for crane runways. A section of the machine shop, 120 feet by 28 feet, is devoted to tool room work, die sinking and metal pattern making. Every modern facility in machinery and equipment has been provided, both in the tool room and the machine shop, to augment the rapid and accurate production of every variety of work passing through the many departments.

It is interesting to note that no small number of the larger machines, used on special parts of agricultural machines, were designed and constructed at this plant. Some conception of the possibil-

This view shows the general layout of the plant. Following are the key numbers to the various buildings. 1. Administration; 2. Machine shop gas engine department; 3. Axe, pick, hammer and storage; 4. Blacksmiths' Shop; 5. Stores; 6. Boiler Shop; 7. Power House; 8. Engine Room; 9 Experimental Dept.; 10. Pattern Making and Storage; 11. Fuel Oil Storage; 12. Foundry Sand Storage; 13. Stores; 14. Rumblers; 15. Foundry for Steel, Cast Iron, Brass and Aluminum; 16. Foundry Stores; 17. Stables; 18. Rolling Mill; 19. General Stores; 20. Lumber Yard Office; 21. Track Sales; 22. Watchman's Office; 23. Printing Department; 24. Gas Engine Testing Dept.; 25. Pumping Station; 26. Machine Storage; 27. Coal Trestle.

ities of the plant may be had from the fact that the 12-inch and the 9-inch mills are being built entirely in the shop, the foundry supplying the necessary castings and the machine shop doing the finishing. To permit the work of building the mills quickly, and at a future date facilitate the repair and maintenance, a new design of mill housing has been developed by the engineer of the plant, and one of the views shows how the open side planer handles four or more of these pieces at one setting.

### Gasoline Engine Department



The gasoline engine department, located in one end of the general machine shop, is 133 feet by 110 feet, and the greater number of the machines are of special character particularly adapted to the duties they are to perform. The design and the development of these machines were carried out by the plant engineers. The purpose has been to provide equipment that will handle the product quickly and economically, on mass production, for the sizes of engines mostly in demand by the farming community throughout Canada, these sizes ranging from 1½ to 12 H. P. All engines are subjected to endurance tests before leaving the factory, a special building being devoted to this work. Adjoining this department is the paint section where the engines are given the final finishing touches before being crated and shipped. A railroad siding runs parallel to the shipping platform.

Immediately adjoining, and parallel to the machine shop, is the new building just completed to house the axe, plow tempering, grinding and finishing departments, together with the smith shop and the general stores. In common with other departments the equipment of the axe shop is of special design, developed by the plant engineers, and, in every way, the work produced has been highly efficient and economically manufactured. The large press shown herewith, for forming the eye of the axe, is of special interest.

### The Rolling Mill

As already stated the product from the mill will provide all the necessary bar and structural material used in connection with the machinery and equipment made in the plant. The mill building, which is approximately 450 feet long by 126 feet wide, is of steel, brick and reinforced concrete construction, with a crane operating throughout its entire length, thus facilitating the handling of the material, and the placing and removal of the different rolls, and likewise the maintenance and repairs to all equipment. For breaking down the ingots a 20-inch three-roll high train is installed, operated by a 1,000 H.P. D.C. motor, driving through double helical reducing gears. The 12-inch mill, and the 9-inch Belgian mill, are operated by D.C. motors of 500 and 350 H.P. respectively. Each mill is supplied by the necessary furnaces, hot beds and finishing racks.

The foundry is casting 8-inch ingots of special steel, which are broken down in the 20-inch mill and afterwards rolled to the necessary section on the smaller train of rolls. From the mill the finished steel is placed in the steel storage department, located at the end of the main forge, being taken from there as required, cut and punched in the press department, forged and necessary hot work put on in the main forge, passing from there to the wheel and erecting section to be assembled, and then transferred, by means of a continuous elevator, to a two-storey paint department, constructed of reinforced concrete, 100 feet by 100 feet approximate dimensions. The warehouse, 225 feet by 75 feet, two storeys, adjoining the painting department.

# A New Development of the Heavy Oil Engine

*By F. A. McLean, Canadian Ingersoll-Rand Co.*

FOR power plant service the advantages obtainable from the use of oil engines are briefly: simplification of equipment, a reduction in labor charges, the elimination of standby losses, a saving of space—due to the absence of boilers and accessory equipment—and a simpler and more convenient fuelling problem, representing in their entirety a much lower cost for power output.

Plant owners and engineers have paid close attention to the story of oil engine development, which within the last few years has been one of gradual transition from the Stuart or Diesel type, with its well-known high fuel economy, but poor flexibility in starting and stopping, and necessity for operating on high temperatures and at high pressures, with consequent trouble, due to the inability of the metals obtainable to stand the severity of the service.

Following this came the development of the so-called Semi-Diesel type, which eliminated some of the complications of the earlier type, but introduced others that are equally undesirable. In comparison with the Diesel type it has a much lower operating economy; consumes more lubricating oil; is difficult to start, and requires the use of a blow torch for the preliminary heating of a hot plate, cap or bulb, for ignition purposes.

Numerous attempts have been made by different designers to overcome the objectionable features of both the Diesel and the Semi-Diesel types and to develop a low compression engine possessing high operating economy.

The Ingersoll-Rand Company along with others entered this field, made an extensive study of heavy oil engines and, as a result of their researches and experiments, recently placed on the market a line of stationary and marine oil engines of a distinctly new type.

These new engines are different from any other oil engine on the market, being neither of the Diesel nor Semi-Diesel type, although it is asserted that they possess the advantages of each type with none of their disadvantages. They are known as the Ingersoll-Rand, Price Rathbun type, heavy oil engines, and operate with highest economy on a new principle, which permits their simplification to a remarkable degree. Engineers who are familiar with the extreme simplicity of the ordinary gas engine, can well appreciate what has been done in this line.

In the past, heavy oil engines of high economy have operated on cylinder compressions of between 500 and 600 pounds air pressures of approximately 1,000 pounds per square inch being used for the injection of fuel, thus requiring the use of a two or three stage air compressor attached to the engine itself, or separately driven. In either case the power required to operate them amounted to at least 10 per cent. of the total power output and they required considerable attention on the part of the operating force. All this troublesome and inefficient air injection equipment has been eliminated in this new engine, and it has demonstrated some things heretofore considered impossible.

In a rigid 72-hour test conducted a few months ago a three-cylinder engine built for central station service in Cuba showed at full load an average fuel consumption of 0.425 pounds of fuel per brake horse-power hour, with a compression pressure of less than 200 lbs. per square inch. At three-quarters load the average fuel consumption was 0.45 lbs. and at half load 0.51 lbs., the oil used being of 28° Baume. In considering the fuel economy of this engine (approximately 0.4 lbs. per brake horse-power hour), it is interesting to remember that in marine practice it has been customary to give fuel economies on the basis of indicated horse-power, and inasmuch as the mechanical efficiency of a Diesel engine is about 75 per cent., 0.4 of a pound per brake horse-power is equivalent to 0.30 lbs. per indicated horse-power hour for the Diesel engine.

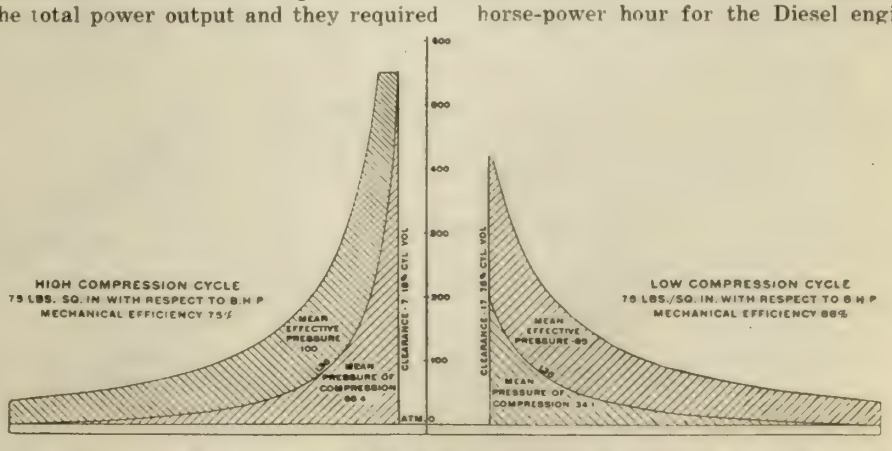

FIG. 1 DIAGRAM ILLUSTRATING MARKED DIFFERENCE BETWEEN HIGH AND LOW COMPRESSION CYCLE.

In other words, the Diesel engine would have to operate at 0.30 lbs. per indicated horse-power hour to equal the figures given for the new engine.

### Cycle of Operation

The engine operates on the four-stroke cycle, with low compression (approximately 200 lbs. per square inch), with direct fuel, or as it is sometimes termed, solid fuel injection, and is absolutely independent of hot tubes, bulbs, caps and starting torches, nor is it a surface ignition engine.

The inlet valve is opened mechanically and the piston travels downwards on the suction stroke, drawing in a full charge of pure air. The intake valve is closed by its spring and the piston returns, forcing the air from the cylinder into the combustion chamber and compressing it to a pressure of approximately 200 pounds per square inch.

Injection of fuel starts near the end of the compression stroke and is completed before the piston reaches the end of its travel. Perfect working stroke combustion at constant volume occurs almost exactly at dead centre, the pressure rises from 200 to approximately 400 lbs. and the piston moves downward on the working stroke.

Near the end of the working stroke the exhaust valve is opened mechanically, the pressure drops, and the piston expels the burnt charge on its return.

### Various Cycles

The cycle of this new P. R. engine is closely related to that of the ordinary four-cycle or automobile engine, and the marked difference between this cycle and that of engines of the high compression type is clearly indicated by Figure 1, while comparative indicator cards for the Diesel, the Ingersoll-Rand, and a Corliss engine are shown in Figure 2. It will be noted that the cycle of the new engine falls in between the Diesel and Corliss engine cycle. The ratio between the amount of work delivered by the engine and the amount of work done in the engine cylinder during the compression and expansion strokes is 35 per cent. for the Diesel, 49 per cent. for the Ingersoll-Rand, and 75 per cent. for the steam engine. This ratio may be called "The co-efficient of durability" or "power factor" in the same sense as the expression is used in electrical computations. An alternator which has a power factor of 75 per cent. is performing within itself 100 units of power, of which 75 units are available for use. The life of an engine, the cost of lubricating oil, repairs and attendance required is indicated by this power factor or "co-efficient of durability." In other words we have the Corliss with a high power factor of 75 per cent. lasting for very long periods and requiring very little lubricant, repairs or attention. Next comes the new engine with its power factor of 49 per cent. indicating that it will last 40 per cent. longer and require correspondingly less lubricant and attention than the other, with its 35 per cent. power factor.

### Advantages of Low Compression Cycle

In the Ingersoll-Rand cycle, as already mentioned, the compression is carried to approximately 200 lbs., when combustion at constant volume occurs, raising the pressure to about 400 lbs., at which point almost perfect adiabatic expansion begins. In the high compression type the pressure is carried about 500 lbs. and oil is admitted gradually, so as to produce combustion at constant pressure until the piston has travelled a portion of its stroke, from which point expansion begins. Thus there are four points of particular advantage in the low compression cycle.

First, a lower ignition temperature is required, due to the elimination of the refrigeration action of the injection of air in the Diesel engine, as it expands from 1,000 pounds per square inch down to the cylinder compression pressure. Second, the engine we are discussing does not require an air compressor for fuel injection, friction losses are lower, and—due to its higher mechanical efficiency—the mean effective pressure which is proportional to the net work developed in the engine cylinder for the same brake horse-power of engine need only be 85 per cent. of that of the high compression cycle.

The mean pressure of compression which is proportional to the work done in the engine cylinder during the compression stroke is approximately half that of the high compression cycle, and although it is true that this work is not lost, but returned to the piston during the expansion stroke, nevertheless the performance of this extra work of compression by the piston and the return to the latter of an equal amount of excess work during the expansion strike represents considerably more wear on the piston, cylinder and bearings. For equal brake horse-power the low compression cycle subjects the engine to about 30 per cent. less wear. Parts of equal dimensions will therefore wear considerably longer and require much less attention.

As previously mentioned, the new engine is free from hot caps, tubes, bulbs, uncooled apron castings, etc., an electric igniter being used for the first few ignitions when "starting cold." The absence of hot caps or hot surfaces of any kind is of great advantage in eliminating overheating troubles at full load and underheating troubles at light loads. As there are no highly heated parts, a full charge of air can be drawn in, instead of heated, expanded, and reduced in volume. This is one of the ways in which the higher power attained with this engine for a given piston displacement may be accounted for. The splitting of hot caps is eliminated, the absence of starting torches reduces the fire hazard, and tends to make a cleaner and cooler engine room. The engine being comparatively cool at all points, the operator is enabled to attend to it with greater ease.

### Fuel Supply and Injection

A pump driven from the engine elevates the oil from the main supply to a filter of special construction located at one end of the platform from which the oil is fed to the fuel injection pumps by gravity. The fuel injection pumps, one for each cylinder, are mounted on the housing near the cylinders and operated by cams from the side shaft, which also drives the centrifugal governor used to control the amount of fuel injected and vary the intake of air so as to maintain

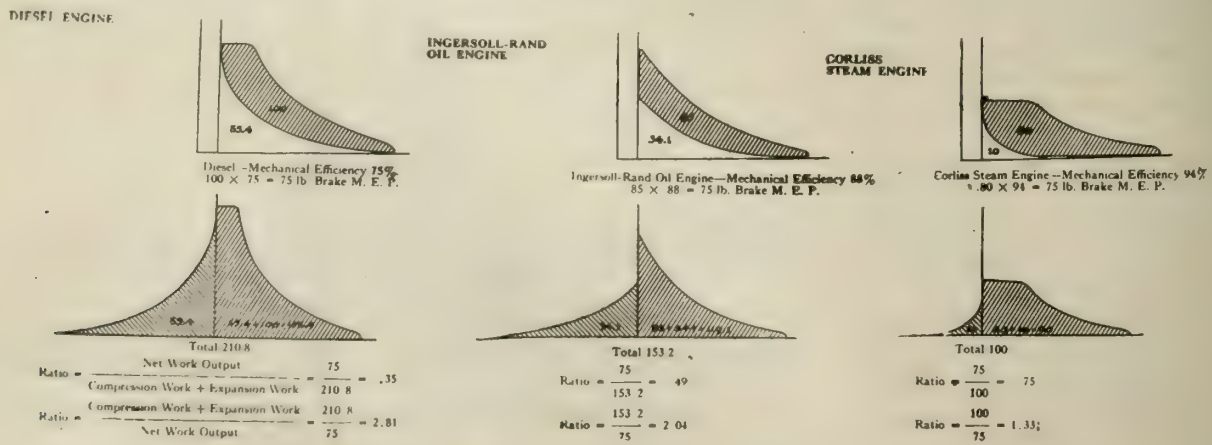

FIG. 2—CHARACTERISTICS OF DIESEL, INGERSOLL-RAND AND CORLISS ENGINE CYCLES COMPARED.

the cylinder temperature under various loads.

Fuel is injected by the fuel pumps without the use of air injection equipment and the economy is said to be just as high, or even higher, than that of the most complicated air injection engine.

The question that will naturally be asked is this: How does the engine operate without injection air? The answer is simple: The fuel injection system used reduces the fuel to such extremely small particles that a tremendous amount of oil surface is exposed to the action of the increasing temperature obtained during the latter part of the compression stroke. The fuel injection system thus pulverizes the fuel to a "fog cloud" and at the same time obviates the impingement of the oil upon the walls of the combustion chamber.

So perfect is the "fog cloud" formed that it has been found possible to inject the oil with the engine at rest, allow the fog cloud to dissipate and then demonstrate that the walls of the chamber were perfectly dry. The fuel sprays are located at diametrically opposite points on the combustion chamber, so that they are not only balanced against each other, but the resulting motion of the "fog cloud" after impact is opposed by the air coming up through the passage from the cylinder to the combustion chamber, as will be noted by referring to Figure 3. Injection of the fuel begins about 40 degrees before compression dead centre and ends about 10 degrees before compression dead centre.

### High Fuel Economy

A statement that one sometimes hears from those who do not realize that economy and dependability are intimately related is that, since the fuel cost of an oil engine is so low, a gain in economy is a small factor, dependability being the principal requisite. Every heat unit in the fuel, however, that is not transformed into useful work must be dissipated in some way. Either through the walls of the combustion chamber or through the cylinder walls to the water in the jacket, or else it is carried past the exhaust valve and its seat during exhaust, or it may disappear as friction in the bearings or cylinders with consequent bad effect on the upkeep and durability of the engine.

If the engine is inefficient, not only is a large percentage of useful fuel wasted, but in getting rid of the waste heat more or less rapid deterioration results. The waste oil must be added to the fuel bill, or paid for in additional lubricating oil required to preserve the oil film on the overheated piston and cylinder walls; or else paid for in the increased amount of cooling water required to dissipate the waste heat and ultimately in engine upkeep. High fuel economy means, therefore, low fuel cost, low lubrication cost, low cost of cooling water, lower cost of repairs and longer engine life.

It is perhaps needless to say that when an oil engine operates at such high economy as does the type described, no carbon will be deposited in the cylinder and that the exhaust will be practically colorless. The cylinders of these engines after long periods of continuous operation are said to look as clean and bright inside as do the cylinders of a high-grade steam engine, and the piston and rings also remain bright and free.

### General Description

The Ingersoll-Rand "P.R." stationary oil engine is of the vertical multi-cylinder, single acting, four cycle type and is offered for general power plant service for either belt or direct connection to alternators, direct current generators, or other classes of machinery. It is said to be especially suitable for driving alternating current generators in parallel and is built at present in seven sizes, with capacities of 105 to 480 brake horse-power. It consists essentially of a heavy base or bed plate, to which is bolted a housing carrying the cylinders with their heads, manifolds and fuel injection pumps.

### Base and Housing

The bed plate is of heavy construction and simple design, cast so as to form a reservoir for the lubricating system. Ribs and broad flanges give rigidity and ample bearing on the foundation. The crank shaft bearing pedestals are also cast integral with the base, as can be noted by referring to Figure 4. The housing which encloses the driving parts and forms the top half of the oil reservoir is a strong ribbed casting provided with ample means for gaining access to the interior. Doors placed at the back directly opposite the crank throws permit easy inspection or adjustment of the driving parts, while a single cover bolted to the front of the engine and supported on swinging hooks, trolleys and slide rails suspended from the platform, permits access to the side shaft, governor, eccentrics, etc. This arrangement is shown in Figure 5. Working stresses in the housing are eliminated by the use of stay bolts or tie rods, which transmit the working stresses from the top of the housing to the bed plate.

### Main Bearings

Four bearings are used on the three cylinder engine and five on the four cylinder size, and as there is perhaps no other one feature in the design of the vertical multi-cylinder oil engine that has more to do with its mechanical upkeep, the main bearings of the engine have been designed along lines which ensure true and permanent alignment, and provide for quick and easy adjustment. As shown in Figure 4, the bear-

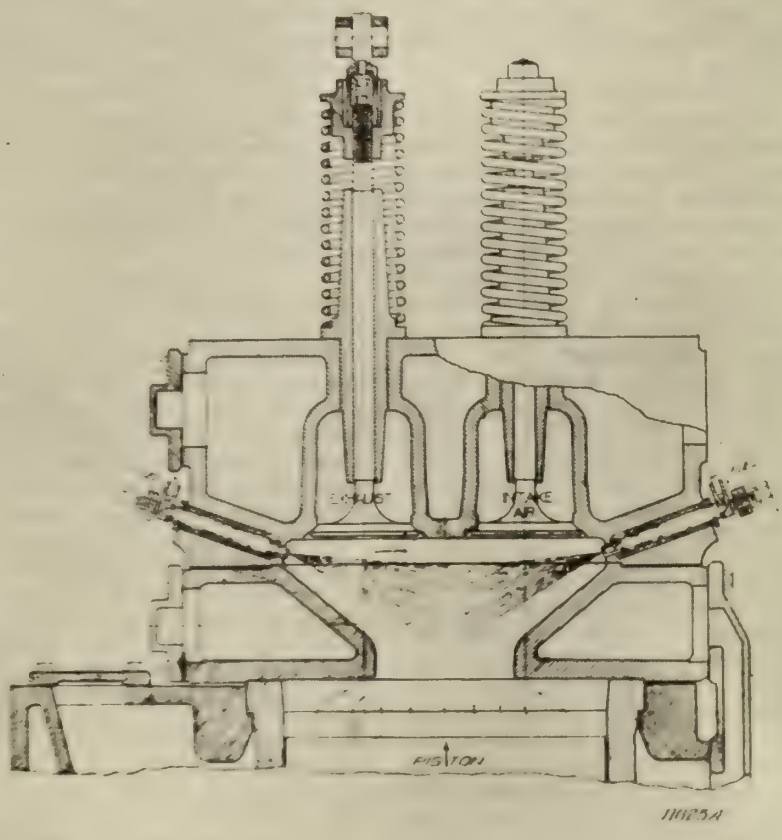

FIG. 3—CROSS SECTION OF COMBUSTION CHAMBER SHOWING LOCATION OF FUEL INJECTION NOZZLES AND MOTION OF FOG CLOUD.

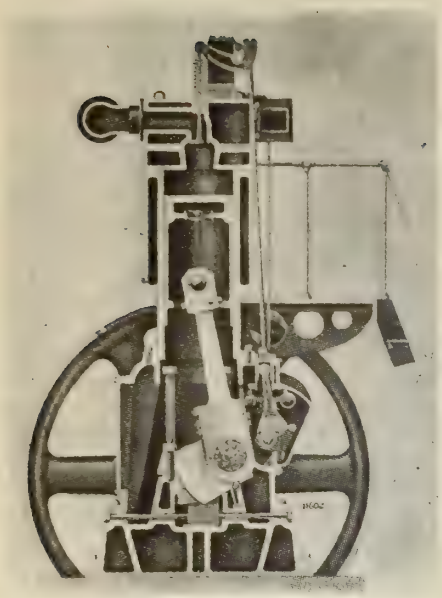

FIG. 4—CROSS SECTION OF P. R. STATIONARY OIL ENGINE.

ing caps are bolted securely to the bed plate; the bottom halves are held rigidly sidewise in the bed plate and supported on wedges which are adjustable from the outside by wedge bolts. By shifting the wedges the bottom half of each bearing may be raised until the shaft is brought into contact with the firmly held bearing caps, securing perfect alignment. The wedge bolts are then tightened and prevent further movement. By removing the wedge and bolts any one of the lower bearing caps can be taken out and renewed without disturbing the other parts of the engine.

**Cylinders and Heads**

The cylinders are semi-steel castings, well water jacketed and supplied with conveniently located clean-out holes. The cylinder and cylinder head water jackets are connected by outside manifolds in place of the more usual jacket to jacket connection. This permits the use of metal to metal joints and eliminates troublesome gaskets and packing at points of high pressure.

Cylinder heads are in two parts, the intermediate head forming the combustion chamber and carrying the compressed air starting valve and starting element and the main head, containing fuel injection, nozzles, air inlet and exhaust passages and valves.

**Pistons**

The pistons are cast from a special material designed to withstand wear and avoid warping. They are carefully finished and fitted with a "fire" ring near the top, three beveled rings held by bevelled segments and flat springs near the middle and a wiper ring in the skirt. The latter prevents an excess of crank case oil entering the cylinders, or used cylinder oil entering the crank case. Surplus lubricating oil in the cylinder is conveyed to a separator and vented to the atmosphere.

**Valves and Valve Motion**

Valves are of the poppet type located in the head, as previously mentioned and are operated through a valve motion known as the "roller path type" from eccentrics mounted on the side shaft. Timing of the valves and fuel injection is obtained from this side shaft through the medium of a pair of spur gears driven by the crank shaft and the entire valve motion and timing mechanism works smoothly and quietly.

**Crank Shaft and Connecting Rods**

A solid one-piece steel forging is used for the crankshaft, ensuring uniform strength and stiffness. The connecting rods are forged from mild steel with a solid eye and adjustable bronze box at the wrist pin and a babbitted steel half box and a babbitted steel strap bolted and keyed to the rod at the crank pin end.

**The Fly Wheel**

The flywheel is of the split hub type, massively constructed and acts as a strong and rigid coupling between the main shaft and the extension shaft, the dimensions of which vary according to the requirements of each installation. A self-aligning outboard bearing provides additional support for the extension shaft.

**Lubrication**

As previously mentioned, the bed plate and housing are arranged to form a reservoir for the automatic lubrication system. Adjustable dippers on the connecting rods dip into the oil at each revolution and drench the working parts with oil. Troughs on the inside of the housing catch part of the oil and convey it through pipes to the main bearings. In operation, oil from an elevated filter is supplied to the main bearings through open sight feed oilers, insuring a constant supply while the engine is running. The oil level in the base is adjustable and the overflow is returned to the filter by a small pump.

**Starting**

Electric ignition—by means of a small element in the combustion chamber, heated to a dull red—is employed for the first few revolutions, when the engine is absolutely cold, while compressed air from a tank under pressure of 150 pounds is admitted to each cylinder in succession by means of mechanically operated starting valves and serves to turn the engine over. As the engine is turned over fuel is injected and after a few revolutions the air and ignition are cut off and the engine continues to ignite entirely by compression. Where compressed air and electricity are not available for starting purposes they are usually provided by a small gasoline or kerosene oil-driven compresser and a belted generator.

## FARM MACHINERY PLANT

(Continued from page 36)

temporarily installed in the press shop, has been responsible for the fabrication of all the columns and roof trusses and general steel work necessary in the construction of the new buildings, as well as the steel flume pipe for the electric development power station that supplies the rolling mill with power. This hydro-electrical development consists of a concrete dam 150 feet wide by 75 feet high, 1,700 feet of wood stave pipe, 6 feet in diameter, and 360 feet of steel pipe between the dam and the power house, which is situated 20 miles from the plant. This dam was completed on the 4th of December, 1920, and it is estimated that the power station will be completed and current delivered by the middle of January. This work has been carried out by the Corporation D'Energy de Montmagny, F. L. Gagon being the consulting engineer; the latter is likewise chief engineer of this company.

The electrical current will be delivered to the rolling mill power house at 55,000 volts, there transformed down to 550 vots and then, by means of Westinghouse rotary converter to 250 D.C. for the mill motors and cranes. The electrical power for the shops is generated by the plant's own power house. Three Wickes vertical boilers are installed for this purpose, each with a rated capacity of 300 H. P. The electric equipment consists of two 500 K. W. General Electric generators, driven by Bellis and Morcom compound steam engines; one 1,000 K.V.A. rotary turbine generator made by the Allis-Chalmers Company, excited by a Westinghouse motor generator set. There is likewise one D.C. generator driven by a Curtis turbine. Connection is made from the local power plant to the rolling mill switchboard so as to provide for the operation of the mill in case a breakdown occurs along the transmission line from the hydro-electric plant.

The forge shop, containing rope, board and steam drop hammers, Bradley hammers, bulldozers, upsetters and bending machines, rake tooth furnaces and tempering tanks, is designed to handle all classes of work comprised in the agricultural line.

The wood working section of the plant's operations is at present being carried on in a building somewhat removed from the main works, but a site has been allotted near the new rolling mill for a thoroughly up-to-date wood working shop and drying kilns, and it is the intention to proceed with this structure as soon as the snow is off the ground.

A malleable iron foundry is also in course of construction which will supply all the malleable iron castings required for the various implements.

From the foregoing description it will be seen that this plant, with the exception of fuel and raw materials, is practically self contained. At a later date we intend showing interesting operations as performed on this class of machinery.

# Calculating Foundations for Machinery

## Causes of Vibration—Vibration as Affected by Degrees of Freedom—Vibration in a Body With One and Two Degrees of Freedom, and the Basis of Foundation Design

By N. W. AKIMOFF

THE WEIGHT of the Great Pyramid is approximately 5,274,000 tons, its base is 764 ft. square, and its height about 486 ft. It is built on leveled rock. The Washington Monument rests upon a bed of fine sand 2 ft. thick. The piers of Brooklyn Bridge are founded 44 ft. below the bed of the river upon a layer of sand, 2 ft. thick, which rests upon bedrock. The massive St. Isaac's Cathedral, Petrograd, is built on a swamp, and the piling has been so carefully proportioned that the exceedingly heavy doors of the cathedral swing easily, whereas the slightest lack of uniformity in settling would doubtless lock them. These well-known structures are here mentioned by way of illustrating the obvious purpose of the foundations upon which they rest. The object of such foundations is double: (1) To distribute the load in as nearly uniform a manner as possible; and (2) to secure uniformity in settling, it being a well-known fact that all heavy structures settle, some to a considerable extent, 6 to 12 in. and sometimes even more.

Just how all this applies to foundations for all sorts of machinery, and in particular to rotative machinery, is not easy to say. Indeed, the weight, say, of a large pumping engine or of a turbo-generator outfit is generally much lower per square foot of floor space occupied than the limits prescribed by municipal laws or building ordinances, and furthermore, uniformity of settling of a relatively small volume of this nature (substructure plus engine, etc.) can be secured without going to the extremes usually observed in designing footings for buildings.

What, then, would be the general governing idea in proportioning a foundation, say, for an engine of a given type? Should it be heavy or light? Should it be deep, resting on rock or sand if possible? Should it be independent of the footings of the building, or would it be desirable to tie it to the latter?

By examining the existing records we can find a great variety of rather contradictory answers to each question, but the predominant idea in the mind of the designers appears to be somewhat as follows: Since the engine is likely to vibrate, let us tie it as firmly as we can to the earth itself. The mass of the earth being practically infinite, the amplitude of the resulting vibration will probably be zero. The designer may be utterly unconscious of this reasoning, but he applies it through instinct or "horse sense" and gets results which sometimes are satisfactory and sometimes exceedingly poor.

It is especially interesting to see how the same designer, having decided to provide as solid a foundation as practical considerations allow, will often unconsciously neutralize his whole theory by such means as: (a) resting the foundation upon a layer of rubber, cork, felt, or other yielding material (see Fig. 1, A and B); (b) providing a space between the foundation of the walls of the building and filling it with sand (if the foundation is so heavy and so deep as to secure immunity from vibrations, why fear its contact with the walls?); (c) using various pads, buffers, cushions, etc. (see Fig. 1, C and D), which, if at all yielding, of course tear to the ground the very idea of solidity of the foundation of the earth.

### Causes of Vibration

A rational basis on which to work is thus seen to be lacking and it is accordingly the object of this paper to point out some definite lines along which a rational theory of substructures for engines and moving machinery can in general be built up. To begin with, it is important to realize that vibrations are caused by two distinct orders of agencies: (1) Those due to unbalance, or, more correctly, lack of running balance; and (2) those due to causes other than unbalance.

As regards unbalance, it may be said that this can be so easily corrected in the construction of machinery that all specifications should invariably call for perfect running balance at all speeds, that is, complete absence of tremor or of "periods" under all conditions. The writer feels that such a complete practical solution of this problem of balancing has been offered by him for bodies of all kinds that there is now absolutely no excuse for the manufacture of unbalanced machinery. However, there are many causes quite independent of balance, each of which is likely to result in vibrations, as for instance, "whipping" of a slender body (crankshaft, arma-

*Paper presented before American Society of Mechanical Engineers.

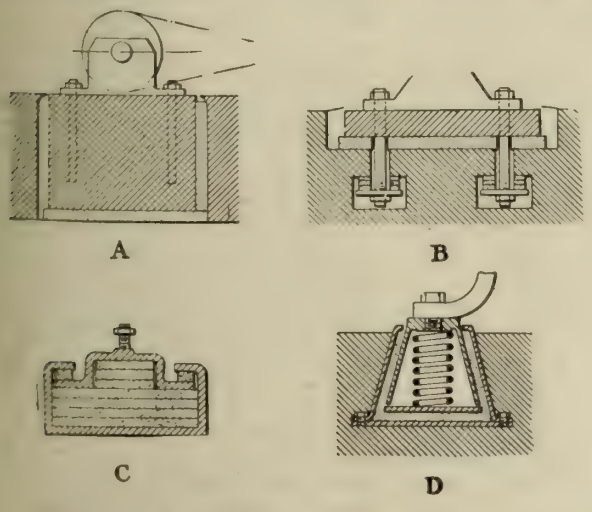

FIG. 1—SOME COMMON METHODS OF NEUTRALIZING VIBRATION.

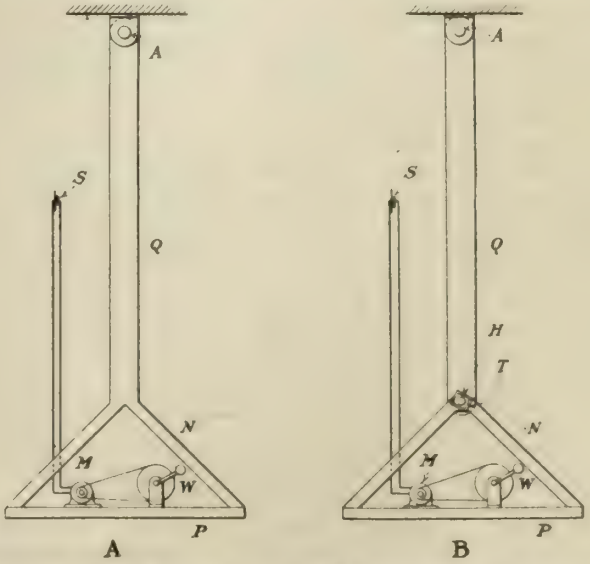

FIG. 3 A SYSTEM WITH ONE DEGREE OF FREEDOM; B SYSTEM WITH TWO DEGREES OF FREEDOM, ONE OF WHICH MAY BE SUPPRESSED.

ture, turbine rotor, etc.); water in a steam turbine; peculiarities of the reciprocating mechanism,—for instance, a 4-cylinder or an 8-cylinder V-type engine where certain forces do not cancel out and where running balance alone is not conducive to perfect results; or torsional vibrations, which under certain conditions produce an effect very similar to that of unbalance. Our problem, then, is to analyze the effect of these various causes, with the view of designing a substructure for a given machine that will be least responsive to these causes, for this is what the "relative" freedom from vibrations really means.

But whatever may be the cause of vibrations, it is safe to say that in general they are always due to forces, acting in a plane or planes, perpendicular to a certain axis, also to centrifugal couples, located in a plane, rotating about a certain line, usually the axis mentioned just above. We know from elementary mechanics that any motion of a body can be resolved into six distinctly separate motions: three along the three mutually perpendicular axes drawn through any point, within or without the body, and three about these same axes. A free body, capable of displacement in any of these six modes, is said to possess six degrees of freedom.

### Vibration as Affected by Degrees of Freedom

If the body is rigidly locked so that no displacement of any kind is possible, we say that all six degrees of freedom have been suppressed. By fixing two points in the body we have the effect of rotation about an axis, and only one degree of freedom, that is, the angular displacement about the axis, characterized by these two points. By fixing one point we suppress all bodily motion along any three axes through this point, but we still have three degrees of freedom, that is, freedom of angular displacement about any or all three axes. Fig. 2 shows a body whose point O is fixed. Such a body can have only three kinds of displacement: (1) about the axis y, as shown by the arrows a or b; (2) about the axis z, as shown by arrows c or d; and (3) about the axis x, as shown by arrows m or n. It makes absolutely no difference what the forces are which act on the body, no other motion is conceivable.

On the other hand, placing a body upon a thick sheet of yielding material, or for that matter on four springs, means freedom in all six directions; and of course the same applies to cushions or pads. For this reason it appears to be of extremely questionable value to interpose layers of such material between a massive sub-foundation and the foundation proper of a machine, even if isolated examples are on record where such an arrangement actually happened to give satisfactory results.

### What Is Stability?

With the foregoing in mind, let us digress for a moment. Stability with regard to our subject is a somewhat relative term. Why was the Great Pyramid built upon leveled rock, even, we are told, dovetailed therein? To insure stability. Why is a ship's compass or barometer mounted in gimbals? To insure stability. Why build a massive foundation for an engine? To insure stability. Why provide a layer of yielding material or springs or rubber pads? To secure stability. In other words, it is quite necessary to define in a more rational way the purpose of a foundation for an engine of a given type. We shall attempt to do this, first stating, however, the well known effects of vibrations on various types of apparatus

In large power plants where the main units are of the modern turbo-generating type the steam mains have been known to burst, and subsequent investigation has often revealed no defect in either material or in general arrangement of piping. The accident can thus only be explained as due to "rough" running, that is, vibrations. What, then, would be the remedy? To anchor the unit still firmer, or to place it on more yielding substance, thus encouraging the effect commonly known as "flopping around"?

The operation of a printing plant or of a leather-working factory is often extremely unpleasant for adjoining dwellings, and sometimes even for buildings located at a rather considerable distance. Inspection often reveals the machinery in such plants as firmly secured to extremely massive foundations and the owners are at loss as to how to remedy the trouble.

Within the building itself, irrespective of the effects on neighboring properties, the action of machinery is often felt and has been known to cause a great deal of annoyance and dissatisfaction. In addition to the printing press and the leather-surfacing machine, the types of machinery usually apt to cause trouble are as follows: triplex pumps, ice machines, air compressors (direct-driven), and various types of purely rotative machinery, such as blowers, centrifugal pumps, etc.

An internal-combustion engine often exhibits a certain amount of vibration which can be felt all over the understructure. In fact, owing to violent vibrations some of the tie rods, lamp brackets, etc., on automobiles have been known to snap in two, and in aircraft some of the instruments to drop off the board, yet these were parts of the understructure, to which they, as well as the engine itself, were firmly secured. The point we wish to emphasize is that in an understructure too much rigidity is as harmful as too much freedom to yield.

### Stability Defined

We are now ready to formulate the new criterion of "stability" for foundations. Stability is here characterized by remoteness of the operative speed from any one of the several synchronous speeds at which the frequency of the operative speed would be nearly, or exactly, equal to the frequency of the free oscillation of the system, if displaced from natural state of rest and let go.

How many distinct synchronous speeds a system is capable of having depends upon the number of degrees of freedom. An absolutely free system, for instance, placed upon an elastic sub-foundation, may have six independent synchronous speeds, or "critical" speeds, as they are sometimes called. A massive foundation resting upon rock is likewise often apt to be, in the larger sense, free in all six degrees, since it occasionally does vibrate and propagates the vibration to other buildings, etc. A system with one fixed point may have only three such synchronous speeds, while a system mounted to rotate about an axis can have only one such speed or "period," such as it is often termed. If we could control these synchronous speeds, so as as to make sure that none comes anywhere near the actual speed of operation of the machine, we would then have a fairly complete solution of our problem.

### Vibration in a Body With One Degree of Freedom

In order to understand clearly the foregoing as well as the broad methods here proposed, let us consider the following experiment and the general consequences manifestly derived therefrom. Imagine a pendulum (Fig. 3-A) consisting of a platform P rigidly connected to the member Q by means of the side members N. The system is free to swing about the axis A in the plane of the figure. A small motor M fastened on the platform P operates a countershaft carrying an off-center weight W. The motor is fed through a suitable flexible connection and it is always possible to adjust the speed of the countershaft carrying the weight W so that the number of revolutions per minute of the former will be equal to the number of double oscillations per minute of the pendular system, if the latter is slightly displaced from its vertical position of equilibrium and let go The effect of this adjustment of speed will be the so-called "synchronism," and the extent of swing (amplitude) of the pendular system, in general very slight for arbitrary values of the rotative speed of the weight W, will now become violent, in fact, out of all proportion to the magnitude of the weight W itself

This phenomenon of synchronism of cause and effect has been well studied The amplitude at the exact condition of synchronism should theoretically be infinite, but of course in practice resistances of various kinds are always present, so that instead of infinite we have large amplitudes. The most curious fact is that in the vicinity of synchronous speed, both above and below, the amplitude drops down to a value almost

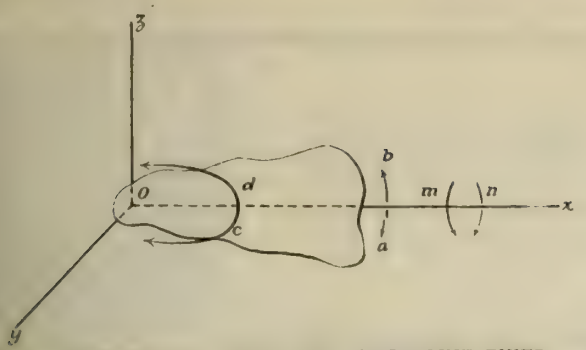

FIG. 2 DIAGRAM OF A BODY WITH ONE POINT FIXED.

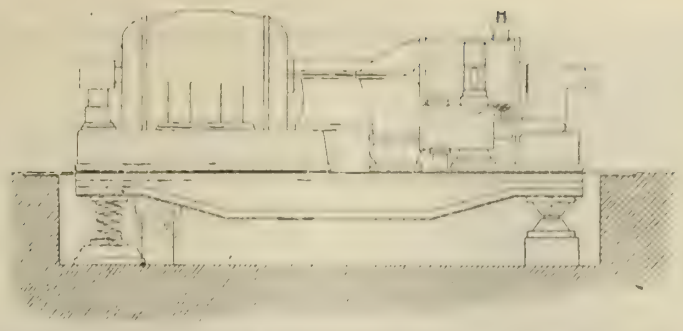

FIG. 4 APPLICATION OF AUTHOR'S DESIGN TO A TURBO-GENERATOR

insignificant, so that if the weight W is small the system appears to be practically at rest. Furthermore, any further increase of speed will not produce any effect, contrary to the current opinion of those not very well versed in the matter. For the sake of illustration let this synchronous speed be 100 r.p.m.

### Vibration in a Body With Two Degrees of Freedom

As a modification of the experiment let us now provide another system (Fig. 3-B) identical with the first except that the platform P is not solid with the member Q but is pinned thereto at H, the pin used being both frictionless and at the same time so arranged that it can be tightened up by means of the nut T, so as to lock the joint, thereby securing the exact effect of the rigid pendular system of Fig. 3-A. Providing the pin H in the language of dynamics is the introduction of an additional degree of freedom, thus securing a system of two degrees of freedom; while the tightening of the nut T, amounts to suppressing one of the degrees of freedom, thus converting a two-degree into a one-degree system. In experimenting we shall first deal with the system of one degree of freedom, tightening the nut T and thus converting the pendulum into a system exactly similar to that discussed above, the synchronous speed being, say, 100 r.p.m. The pendulum will oscillate violently. We now loosen up the nut T, introducing an additional degree of freedom, with the apparently surprising result that the amplitude decreases practically to zero. If we reduce the speed considerably, say to 50 r.p.m., violent oscillations of the whole system will reappear, as will likewise be the case in speeding up the countershaft, say to 150 r.p.m. These figures are purely illustrative; whether they will actually correspond to exact facts will of course depend upon the characteristics of the system.

In other words, by introducing an additional degree of freedom we have accomplished this double result: (1) What was synchronous speed for a system with a single degree of freedom is no longer synchronous speed for the same system provided with an additional degree of freedom; (2) the new system has two frequencies of oscillation, at which it is sensitive to disturbing influences (such as centrifugal action of the weight W), one being below and the other above the value corresponding to that of the same system with the additional degree of freedom suppressed.

It should be especially observed that the oscillations were thus reduced practically to zero, not by steadying the system by something without it, but by some sort of an adjustment wholly within the vibrating system itself. Furthermore, what we did was to increase in a measure the flexibility of the system by breaking it in two; and although at first glance this might have increased the effects of the disturbing agency (rotation of off-center weight W) the actual effect was practically to bring the system to rest. It is still more important, however, to note the fact that we introduced the additional degree of freedom precisely in the sense of action of the disturbing agency, that is, in the sense of the plane of the figure and not at right angles thereto; or, say, in an up-and-down sense, as for instance by providing a coil spring instead of joint H.

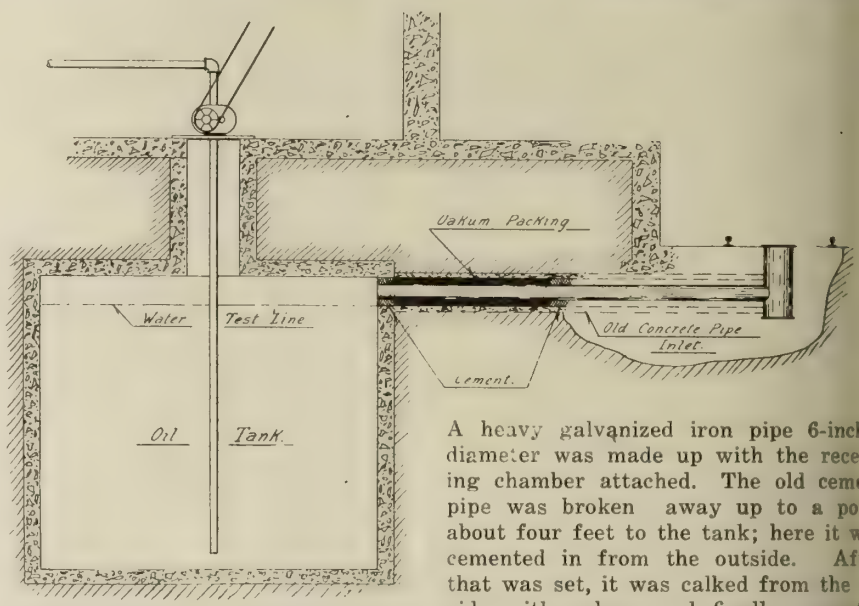
### The Basis of Foundation Design

This, then, will be taken as basis for our further discussion: In contemplating the design of a foundation we shall always separate those directions (or axes of instantaneous rotation) about which the system cannot (or at least is not likely to) oscillate from those directions (or instantaneous axes) about which the system is more or less certain to vibrate. We next shall select a "steady" point from purely practical considerations, and finally devise such means of controlling the "free periods" of the system as will secure the desired degree of remoteness from synchronism under the actual operative speed. Such means of course will be springs, exceedingly heavy, and not in the least calculated to allow of any free wabbling of the system. They will also be adjustable so that the desired periods may be readily varied within wide limits; and in general structurally arranged to introduce as few changes as possible in the arrangement as a whole.

The author feels that to submit too many particulars as regards the detailed designs of such an arrangement would certainly defeat the purpose of this paper, which is merely to introduce the broad idea and not any one of the scores of individual designs which might readily suggest themselves to the engineer confronted with the problem of designing a foundation for a given machine. Considering, therefore, only one type of apparatus, a turbo-generator (Fig. 4), we must start out with the selection of the steady point. We will naturally place it as near the steam main as possible (not to the exclusion, of course, of a suitable expansion joint), as under all conditions, should there be a choice of position, preference should be given to that point as far as possible from the center of gravity of the system, so that any static unbalance (whipping, etc.), would be made to act not as a force upon, but as a moment about that steady point. Such point should actually be made as steady as possible and no trouble should be spared in providing suitable piling or digging down to the solid ground and constructing suitable footings.

The next problem is to design a substructure adapted to receive the bedplate of the apparatus and made stiff enough so as to eliminate any "periods" of its own. This bedplate may be made of structural steel or of reinforced concrete, in which latter case the ends thereof may be made of cast iron. The substructure is supported upon the steady point either by a ball-and-socket arrangement, or is simply bolted at that point to the floor plate underneath by a bolt which need not necessarily be very light, but which must be arranged in a manner to secure the minimum area of actual contact. Remembering that in apparatus of this sort the tendency to oscillate about the axis x (Fig. 2) is always rather negligible, we have practically only two degrees of freedom and only two periods to adjust so as to have them well out of the limits of the operative speed. Hence the two sets of springs, one to take care of the period corresponding to oscillation in the vertical plane, the other to control motion in the horizontal plane. It should not be imagined, however, that these springs will necessarily be very light; they will always have considerable stiffness, but their function is that of being the only members that can yield and the whole situation is controlled by the proper choice of these yielding elements.

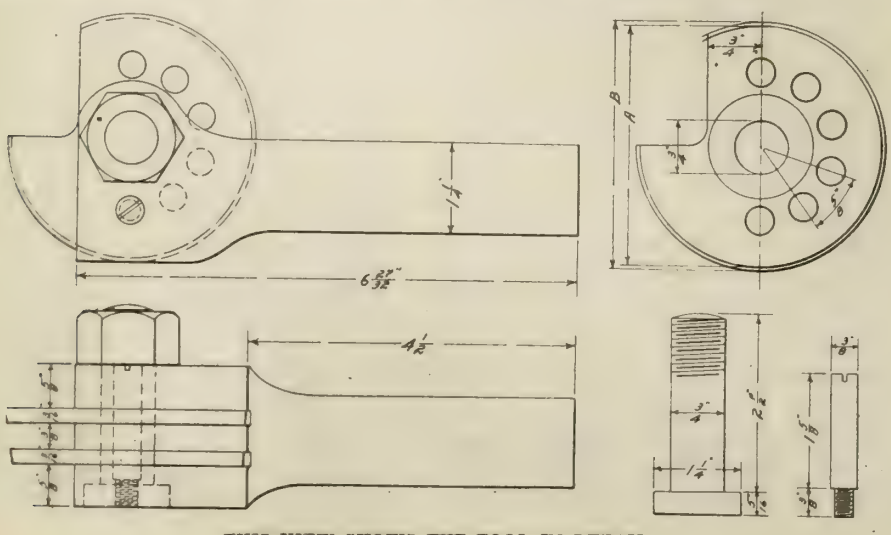
# WHAT OUR READERS THINK AND DO



## FUEL OIL STORAGE TANK

By John Homewood

The accompanying illustration depicts a fuel oil storage tank made entirely of concrete. This tank has a capacity of fifteen thousand gallons and is accessible only through a man hole in the top. A new building was erected over the tank, but either through damage caused in the construction of the new building, or through a slight earthquake, the tank was found to have developed a serious leak. As soon as the fuel oil was exhausted it was decided to have an examination made so as to ascertain the location and conditions of the break.



It is well known that there is great danger prevalent for a man to enter an empty tank that has held crude oil. A battery of three vacuum cleaners was connected to three pieces of 1½-inch pipe that reached the bottom of the pit where the heavy gases lay. These cleaners were in operation for four hours before a man ventured down.

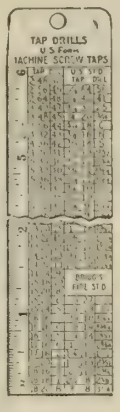
The examination did not disclose anything in the form of a crack or break of any kind. As a leak showed up when the tank was filled, it was decided to give it a water test. The tank was filled to the top with water and measurement taken. In a few days another measurement was taken and the level showed to be in line with the intake. Several days more elapsed before another test was taken, which showed the same level. The intake to the tank was an eight inch cement pipe that led out to the centre of the track so that the tank car could empty into it direct. The excavation as shown was made, which disclosed that the pipe was in very poor condition at the joints and evidence to the fact that the leak was in the pipe. To attempt to repair the pipe was futile, so other means were resorted to.

SECTIONAL VIEW OF THE STORAGE TANK.

There in the tank was fourteen thousand gallons of good water to remove without any means at hand except that we might try converting a pressure blower into a pump. This was attempted with great success and the water was soon removed. Now that we had the water out, and knew where the leak was, we could proceed with the repair. A heavy galvanized iron pipe 6-inche diameter was made up with the receiv ing chamber attached. The old cemen pipe was broken away up to a poin about four feet to the tank; here it wa cemented in from the outside. Afte that was set, it was calked from the in side with oakum and finally cemente from the inside. The new pipe was en cased in a concrete retaining box.

THIS VIEW SHOWS THE TOOL IN DETAIL.

## DOUBLE PARTING TOOL



By Clyde D. Thorburn

Some time ago we illustrated a dou ble parting tool for use in cutting pisto rings from sleeve casting, and the illus tration herewith is that of another dou ble tool for the same purpose. Thi tool was designed so as to have a longe life and would always be standard widt between cutters. It is ground only o top of cutting edge, its design allowin the necessary clearances required. Boc of tool is made from mild steel forgin shaped on all flat surfaces and tw grooves sawn in head to receive the hig speed circular cutters. The cutters a turned slightly concave to insure co tinuous clearance and bevel on cuttin face to make a clean cut-off.

The top tool is turned ⅛ inch larg in diameter than bottom tool. This to allow for sufficient strength of met to hold on the lower ring when partin off upper ring. Six ⅜ holes are drill through the cutters and hole to corr spond through jaws being tapp through one side of jaw to take the r taining pin. This allows for the mo ing of cutters as they are ground ba through wear. The tool can be used the side head of a Bullard vertical ordinary vertical boring mill. We a using it there and find it a distinct a vantage over previous tools.

# Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

## What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

The Prize Winner for December 23rd Issue List is J. A. RUSH, Weston Shops, Canadian Pacific Railroad, Winnipeg, Man. He Had All Answers Correct.

**CONTEST FOR JAN. 20TH ISSUE**

**Contestants are required to write us, stating to which advertisements we refer in this number.**

1—That more than a broken tooth can be removed—and as the dentist would say—without trouble.
2—Something that was redesigned and saved half the former cost.
3—A machine said to have considerable versatility.
4—Something that permits of various kinds of tooling.
5—A portion of a machine that is carefully heat treated.
6—A product that is quickly relocked.
7—That you must vary your cutting tool if you want the best results.
8—A product that is said to prove its quality quickly.
9—How to take the jump out of a belt.
10—Something that is made to stand rough usage.
11—Something that is said to be the understudy of necessity.
12—A product said to work without a slip.

**These are Correct Answers for List from Dec. 23rd Issue:**

1—Geo. F. Foss Machinery & Supply Co.
2—The L. S. Starrett Co.
3—E. C. Atkins Co.
4—Kearney & Trecker Co.
5—Bilton Machine Tool Co.
6—Hendey Machine Co.
7—J. Ackworthie, Ltd.
8—Canadian Link-Belt Co.
9—The Sidney Tool Co.
10—Canada Machinery Corporation Co., Ltd.
11—Nicholson File Co.
12—The Geometric Tool Co.

## Closing Date for This Contest is February 10th

# DEVELOPMENTS IN SHOP EQUIPMENT

## SELECTIVE HEAD LATHES

The Lehmann Machine Co., St. Louis, have placed on the market a line of improved selective head lathes. This geared head gives a large numbr of speeds with very few gears. The tooth travel is moderate at all spindle speeds, thus ensuring quiet running.

There are only ten gears in the headstock which give sixteen spindle speeds, (on 16-inch lathe from 10.5 to 422 R. P. M. and on 22-inch lathe from 8.5 to 330 R. P. M.) These speeds are in almost exact geometrical progression and all obtained without the use of the countershaft. No safety or interlocking device is required to avoid engagement of differing gear ratios at the same time, as design makes it impossible for this to occur.

All gears in the headstock are of heat treated steel of a special selected grade for the purpose. Some of the gears and back gear clutch are carbonized and hardened. All shafts are high carbon steel and run on ball bearings. Shafts having sliding members are made with four keys milled integral with the shaft. All shifting members are operated by a ring which runs in a groove and completely encircles same.

The gear ratio on the 16-inch lathe is 57.1 to 1, and on the 22-inch lathe 70.6 to 1. The other sizes are in proportion.

The spindle, which is made of alloy steel, has hardened and ground bearings and runs in bronze boxes. Where the back gear clutch slides on same there are four keys milled integral with the spindle. There are two diameters on spindle nose both giving bearing for face plates or chuck plates, one bearing being in front and one bearing behind the threads on spindle nose. This makes a very rigid connection of chuck plates on spindle and very greatly facilitates the putting on and removal of same.

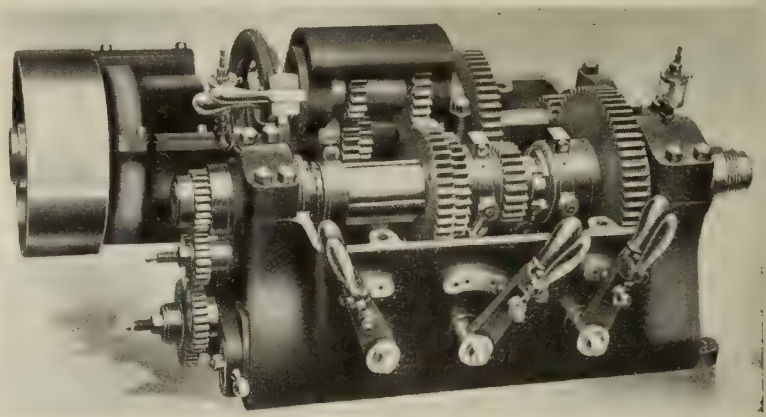


FIG. 2—HEADSTOCK OF LATHE WITH COVER REMOVED.

### Friction Clutches

The friction clutches have forward and reverse, or brake, operated by handle on apron and a similar handle at headstock end of bed. This mechanism is operated through helical spur gears which run in oil and are mounted on shafts having ball bearings. These clutches require no adjustment and are said to always pull a little more than the load imposed. Cover on clutch housing forms an oil tight case and the clutches run in oil all the time. The film of oil covering cone surfaces has to be displaced when clutch is engaged which gives an easy pick-up and practically eliminates any wear. Male cone is made of hardened steel and female cone of cast iron which insures a very long life of these parts. Forward and reverse will engage and disengage very easily with slight movement of control handles and it will pick up whilst under full load without any trouble whatever.

Fig. 3 shows the construction of rocker. The large diameter of its bearings in headstock, and the method for operating same without having openings in head-

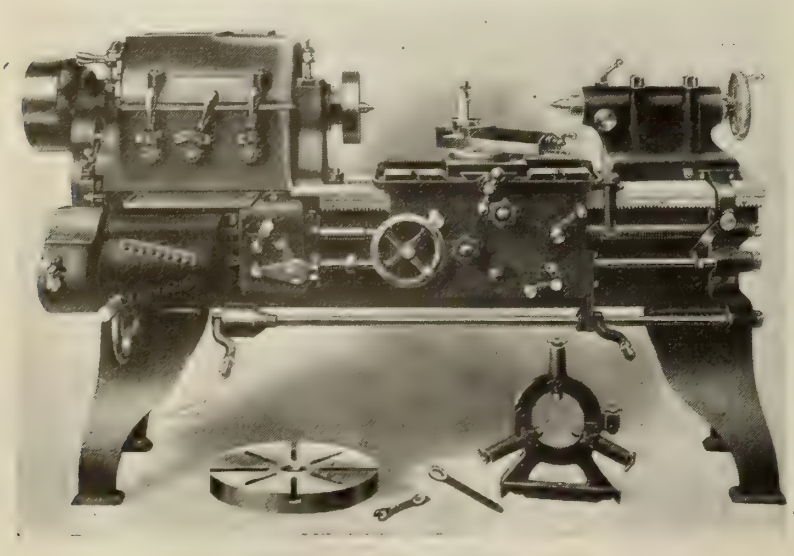

FIG. 1—GENERAL VIEW OF THE LATHE.

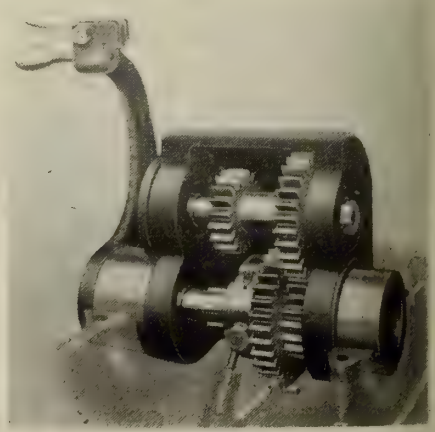

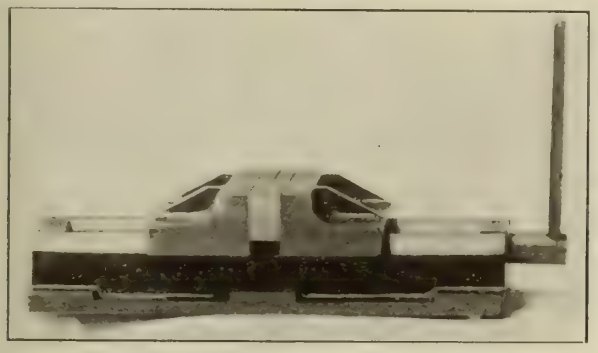

FIG. 3—SHOWING CONSTRUCTION OF ROCKER.

stock for the controlling handle can be noted. This view also illustrates the mechanism for shifting gears. The same substantial device is used for other shifting parts in headstock and eliminates possibility of trouble from this source.

The usual arrangement for direct drive is to mount motor on headstock with drive through belt and idler. This idler runs on ball bearings. With the fast belt travel on these geared head lathes this will be found a very satisfactory application and no trouble will be experienced on account of short belt, the pull on same being much less than is usual on account of the large diameter and high speed of driving pulley. This also permits the use of a high speed motor (1,800 R. P. M.) which makes same smaller, lighter and less expensive. Suitable guard for belt and pulley is provided. The direct drive can also be furnished with motor mounted on a base hinged to leg of lathe. Some users prefer this method of mounting the motor and on this no idler is required. Suitable guard for belt and pulley is provided.

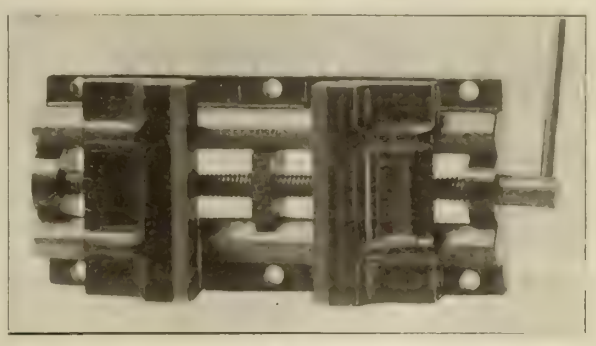
## NEW VISE

The Lang Manufacturing Co., Ltd., Guelph, Ont., have placed on the market

USING THE VISE IN A FLAT POSITION.

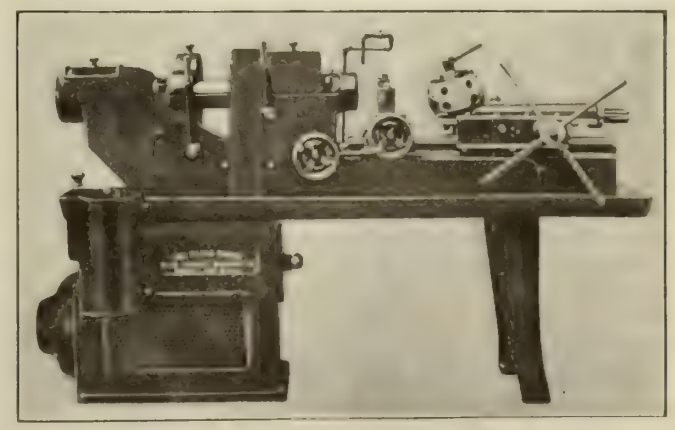
a new type of vise that is said to be especially adaptable for lathe, shaper, miller, drill press, and, in fact, all general uses.

The illustrations herewith show clearly the vise's general appearance. It will be noted that this vise is so constructed that it can be used flat, as at Fig. 1, or on its side, as shown at Fig. 2. This feature allows holes to be drilled at right angles without removing the work from the vise. This vise can also be used on the lathe face plate if so desired, and takes, as it were, the place of the chuck.



Attention is called to the fact that the sides of the vise are bevelled on both sides. This angle is designed so that all cuttings will fall off the slides and not stick and get ground into them.

The concern who manufacture this vise have stated that they have thoroughly tested its efficiency before placing it on the market, having had one under actual working test for over a year. They claim that quick action with increased power is obtained, also that the jaws are always centrally located irrespective of the size of work held. There is said to be a live grip on both jaws, and no loss of power through the usual thrust collars.



It will be noted from Fig. 2, that there is a centre nut which braces and strengthens the power of the vise screw. This nut goes clear to the base. The vise handle is light of construction, yet is amply strong to exert the necessary gripping power.

## MOTOR DRIVE FOR TILTED TURRET LATHES

The improved motor drive illustrated has been adopted by the Wood Turret Machine Co. for use on their line of Tilted Turret lathes and screw machines. It will be noted that the motor base or cabinet leg is so arranged that the motor may be easily removed for cleaning or repairs, by the loosening of three screws that hold the circular lid at the end of the base. The power is transmitted from motor to the main driving pulley on machine spindle by means of a wide leather belt. This belt passes up through the oil pan and is protected from chips and cutting compound by guards which are welded to the pan. Belt tension is controlled by a double acting idler and is operated by the lever shown at the right hand end of cabinet leg. The controller box crank as well as all operating levers are so grouped that they are within easy reach of the operator, without necessitating a change of position. The principal advantage of this type of motor drive is the compact way of mounting and the adoption of an extra wide belt which can be controlled by the double acting idler mentioned above.

ILLUSTRATING THE VISE AS USED WHEN ON ITS SIDE.

GENERAL VIEW SHOWING MOTOR DRIVE.

## AIR LINE SEPARATOR

For the purpose of cleaning the air that is delivered to pneumatic tools, the Independent Pneumatic Tool Company of Chicago have developed a special separator for installation in pipe lines for the removal of dirt and moisture from compressed air. The air from the compressor is forced into the separator so that it strikes the walls of the casing tangentially, causing the air to revolve rapidly, thus throwing the dirt and moisture to the outside wall, whence it falls to the bottom of the chamber, the cleaned air passing on to the main pipe line. Provision is made for draining the dirt and water from the lower chamber. Two sizes are made, 150 and 400 cu. ft. per min.

## Says Conditions Are Better

WHEN Judge Gary, chairman of the U.S. Steel Corporation, states for publication that he can see nothing unfavorable on the business horizon, it carries weight.

"I think I am justified in saying," said Judge Gary a few days ago, "so far as my opinion extends, there is nothing unfavorable on the business horizon. Certainly at present the tendency is toward improved business conditions.

"That does not necessarily mean that there is a decided increase in volume, but it does mean that the general aspect, including the temper of business men, is better. If that continues, it is certain to have a decided improvement within a comparatively short time.

"As before stated, the principal reason for apparent dullness in some lines is that the purchasing public is waiting for such information as will influence it to conclude bottom prices have been reached. It should be evident to everyone that in certain lines or departments further decreases in selling prices are necessary and therefore likely to be reached. I have heard of cases where lower prices have been fixed by retailers than the prices they paid to the wholesalers for the same goods. It shows a disposition to make adjustments which have been determined upon for the purpose of complete readjustments, promptly disposing of stocks and of getting into a financial position which will enable the retailers to proceed in the regular way. And this is only an illustration of what must be done in all lines before we can expect good business.

"However, we all know by experience that after any movement of importance commences, as it progresses it gathers speed and will within a short time reach a momentum that means early completion of the movement.

"I see increasing signs of a disposition on the part of producers and wholesalers to recognize conditions and to submit to such reductions in selling prices as are necessary before a return to a normal volume of business.

"Also, it must be evident to everyone that a large percentage of workmen are disposed and are proposing reductions in wages immediately following the action of their employers to make reductions in their prices. This is a good sign and will have a decided effect. I hope and believe this disposition on the part of employees will be reciprocated by the employers.

"In the steel business to-day those who are buying are buying from the standpoint of necessity and this up to date has secured, for our corporation at least, a satisfactory volume of business considering the times and will, I hope, enable us to continue the payment of interest and the usual dividends. Under these circumstances how could we feel any other than optimistic?"

## Improving Your Time

THERE is something highly encouraging in reports coming from some of the leading technical schools, especially in classes that deal with the practical and advanced practices of mechanics. There are a number of young men out of work now in nearly all the industrial centres. Many of these came into the mechanical field during the war work or shortly after. They had no previous mechanical training, and the munitions shop was a poor place in which to make a man anything like an all-round mechanic. It was the idea that he should learn to do one thing well, and once he had learned to do that one thing well he made good money. But the thing has changed now. There is very little for the handy man to do. Many of the shell-shop mechanics got a liking for this class of work and they are doing the only possible thing now when they have a chance, viz., get on the right path, and start at the start.

Mr. H. B. Beal, principal of the London Technical and Art School, reports that "we find that on account of the shortage of work an increasing number of young men, from 18 to 23 or 24 years of age, who have had some machine shop practice, are coming to the school in special day classes to receive machine shop work and draughting instruction. This movement seems to be steadily on the increase."

There are young men in all the industrial centres who are not hard up. They have no one depending on them and in many cases they have a little surplus.

Right now would be a good chance for them to do the very thing that a number are doing in the technical schools. They are studying. They are finding out the why and the wherefore of the things that used to be beyond them in machine shop practice before because they lacked the training. They are learning to read blue prints intelligently—they are learning in this way the fundamental principles of machine tool design. They might have been able to do a piece of work on a turret lathe before, but they did it as they were told—they can now find out the best way to tool for these operations. They can learn the value of jigs and fixtures to present-day quantity and production, the handling of materials by hoists and the general practice of good machine shop usage.

Investing a few months in this way will bring handsome returns in the future. If your purse will stand the strain, go in for it.

# Sees Great Time Ahead in the Steel Trade

THOSE who are pessimistic regarding business should remember that as far as iron and steel are concerned the world's market is empty in many places.

Syren and Shipping, in an able presentation of Britain's case, says:

"Moderate supplies of both home and foreign iron ores, improved coal output; slightly better pig iron and steel production; downward price revisions; little buying until consumers are quite sure there can be no further concessions; hampered export business through exchange uncertainties; much talk of foreign competition but very little actual competition, owing to restricted outputs in rival countries—such are the surface features of the iron and steel situation.

Fundamental conditions are sound. Amid all the current difficulties and uncertainties, and in face of all the trade slump and foreign competition talk, it cannot, we think, be too often repeated, or too strongly insisted, that Britain stands, ultimately, to gain the most of what there is to be gained out of the unprecedented steel trade conditions created by the war and the war's immediate after effects.

With anything like a return to normal, this country will import more iron ore, and export very much more finished steel, than ever it did, or dreamed of doing, before the war.

### Here Are Four Reasons

The four cardinal points are these:

(1) A world's shortage of steel goods, due to the damages and constructional delays since 1914.

(2) The paralysis of Germany, our greatest pre-war rival, through the loss of the Lorraine and the stoppage of her export subsidization scheme.

(3) The inability of France to exploit her newly-acquired resources through labor shortage and transport deficiencies.

(4) The inability of the United States to meet the world's needs in heavy products through abnormal home demands, excessive transport costs, and the dollar premium, this latter being due to the smallness of American imports.

### America Must Buy More

America may produce the cheapest steel in the world, but she cannot permanently conduct a great export trade in steel, to far distant markets, unless she is prepared to take something like corresponding imports of the products of other countries. Averaged over the 16 leading foreign countries to-day, the American dollar, on the exchange, stands at $1 88. This 88 per cent. premium is a huge tax on American exports.

Out of these four cardinal points arises the fact that Great Britain, with her most convenient raw material supplies, her mines and furnaces side by side, her works close by her docks, and her unique shipping facilities, can beat the world in exportation of heavy steel and engineering products. Our greatest drawback is costly coal. But America is the only rival getting cheaper coal, and this advantage on the side of the United States is offset by long haulage distances for heavy mineral traffic.

**The American coal, iron and steel group of trades have an average inland haul of 500 miles against the British average of less than 30 miles.**

This is no time for panic or pessimism over British trade prospects. It is a time for hope, confidence and a determination to improve our production so that we can obtain that share of international trade to which our resources entitle us.

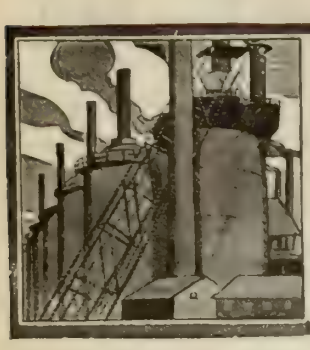
### Time to Go Ahead

Let us convince our workmen of the need for bigger output and then many of our commercial troubles will vanish. In the steel trade, at all events, we have a world to conquer.

The single State of Brazil, on official authority, wants 16,000,000 tons of railway steel alone.

The wants of the Argentine and Chile are little less.

China has hardly been tapped yet as a steel market.



British India wants new railway extensions and equipments exceeding the mileage and furnishings of the United Kingdom railways combined.

The world's steel shortage, due to the war, the war damages and the war delays, whilst so many steel plants were on munitions, is **equal to three full years' production of every steel plant in the world, working at full capacity.**

And this great shortage is additional to the normal wants of the world, amounting to 80,000,000 tons a year before the war and additional to the fresh wants due to the demand for implements and machines to take the place of hand labor, now so costly. Against this huge demand, which will not be relaxed for many years, what are the competitive conditions? They are as already stated.

Germany is not producing at more than half her pre-war rate. The same remark applies to France and Belgium. The entire Continent of Europe is producing no more steel than Germany alone produced before the war. The United States has such an enormous home demand, and has to battle with such long transport distances, and is so prejudiced by the exchange, that she cannot retain, much less improve upon, the trade she secured during the war."

# MARKET DEVELOPMENTS

## Better Feeling Noticed In The Markets

### Business is Still Placed Sparingly, but Many Firms are Now at The Point Where They Will Have to Take on Supplies Very Shortly—Prices Remain Firm in Steel.

IF indications, opinions and summaries are any indication of trade, then there should be an improvement in the near future. Any one who is spending much time calling on the trade can hardly help but notice a more hopeful feeling. Not that any larger orders are being put through, but there is as much trade as there was a month ago. Things are not getting worse in the iron, steel and machine tool business. Occasionally the dealer is met who says plainly that he is doing more business than he was a month ago. Orders for the most part are small, but they are coming in.

Stocks in warehouses and in manufacturing establishments are light. There are only a few exceptions to this and some places still appeal to their dealers to relieve their account by taking back some of this over-stock. This is not being done for the very good reason that the average warehouse is pretty well engaged right now getting rid of all the stock it can in order to take advantage of any better buying opportunities that may open up.

Steel prices hold firm and there seems to be little chance of any break, in fact many of those in the trade go so far as to say that any decided buying movement starting in now would cause a stiffening of prices above present values.

Pig iron is now quoted at $43.64 per ton, being a drop of about $8 per ton from the last figure named. Even at the lower price buying is light in most cases and users will take on just what they have use for in the very immediate future. There has been hardly a start made yet in the old practice of placing order for a year's supply.

The scrap metal market is very weak yet, but some of the dealers can see where they are going to make a start very soon in getting back to more active business. Canadian prices for nearly every grade are higher than those offered at United States points.

## MONTREAL IS LOOKING FOR A BETTER TRADE IN NEAR FUTURE

Special to CANADIAN MACHINERY.

MONTREAL, Que., Jan. 20. — Trade conditions in this district are unchanged although industrial activities in some of the large metal plants have been resumed after a short period of suspension. Little departure from the conservative buying policy of purchasing agents has been noted and, in consequence, trade has not increased. Some little inconvenience has been experienced in the non-delivery of material that has been expected from the Sydney steel mills, but it is hoped that this condition will be rectified very shortly, when the embargo on shipments has been removed. Machine tool business is slow in picking up, slight increase being reported in supply movement. Old materials are still inactive.

**Buying Restricted But Prospects Brighter**

While there is every reason to suppose that the situation in general is less tense than formerly, there is still the attitude of conservatism on the part of the consumer in the purchasing of material and equipment. Buying, of course, is still going on, but in such a way as to emphasize the fact that nothing but what is required for immediate needs is being disposed of by the dealers. The latter, in turn, adopts the same policy, so that the mills are receiving comparatively few orders for future delivery. Some of the producers are kept busy in getting out unfilled orders, and the volume in this respect is becoming appreciably less, a condition which in time will influence the market to such an extent that further inducement, in the nature of lower prices, may be offered to the trade. The stock-taking period of many dealers is now over and some find that they still have considerable quantities of material on hand that were purchased on a rising market and which keeps them from adding further to their stocks even though they were assured that prices were at the low level—a condition that few are willing to accept. Few dealers will deny the possibility of lower quotations, but in face of the continued high cost of production, they cannot see just how a speedy return to "near normal" can be brought about without serious loss to manufacturers and disorganization in many lines of activity.

"We look for a gradual return to more active business but feel that consumers will remain out of the market until the last minute, in the hope that better prices will obtain. Industrial activity will undoubtedly be accelerated from now on, but until labor conditions are definitely adjusted it is next to impossible to expect a resumption of normal operations when everyone is looking for lower prices on all commodities."

Dealers state that business is not brisk but is of a character to encourage renewed interest, as it is thought that much buying is held off only in the hope of easier prices. Should anything develop to give the assurance of a stronger market, buying would naturally follow. Prices here have continued steady but with a weakening tendency. Predictions tend to show that price quotations may be slightly reduced before long.

**Gradual Betterment Expected**

Despite the renewal of operations in many plants, closed for holidays or stock-taking, the call for machine tools has not shown any increase to speak of over past weeks. Some little improvement has developed in the sale of supplies and small equipment, but the volume of business is still below normal. However, we are too likely to accept the term "normal" as meaning the condition prevailing throughout the past several years. As

stated by one dealer in machine tools: "We cannot deny that trade just now is considerably below what it has been during corresponding periods of the past few years, but if the situation is compared with pre-war times, we will undoubtedly find that we have nothing to complain of. We have been so accustomed to heavy turnover that an interval of quiet trading appears like excessive dullness. True, the present is quieter than usual, but it is only the reaction of industrial extravagance. What we need is faith in the future and a realization that the trade is ready to take advantage of the opportunity when the occasion arises." Asked as to the outlook for the year, the dealer stated that it would be exceedingly good and that after a short period of featureless activity, the return would be more marked.

### No Developments in Scrap

"Reports from the outside claim that business is slowly improving but, as far as we are concerned, there has been nothing to show that the old material dealers are sharing in this improvement. We are still on the waiting list." This statement by a scrap merchant goes to show the listless condition still existing in this market, and although they look forward to renewed movement early in the spring, the immediate future does not promise anything but the quietness of the past few months. Quotations are inclined to weaken, but under present conditions prices are not an influencing factor.

## WORKING HARD FOR BUSINESS

### And Some of the Firms Are Getting Results—May See Change for Better in Scrap Market

TORONTO.—Firms are going after business with renewed activity now. In some cases they are getting results. There are cases where the selling arrangements were changed at the first of the year. Salesmen were put on a salary with a chance to make much more on commission if they turned in the business. Salesmen have their own way of looking at these things, and one old timer put it this way: "I have a new contract for this year with a smaller salary but a chance to make it up or more on commission. The only grounds on which I took the contract was that it would be good for a year and a half, and before the end of that time I should be able to cash in on it even if things are none too good at the start."

In small tools as well, agents are working harder than ever before to get business.

There has been a certain amount of business placed by the railroads, but they have not taken on anything like the amount of equipment they are supposed to be contemplating. Complaint still comes from some of the dealers that they are not very particular about some of the railroad business because of the time that elapses between the filling of the order and the forwarding of the money.

Some of the larger machine tool and supply houses, with agencies at several points throughout the Dominion, are more optimistic in their outlook now, as reports from many of the outlying offices indicate that there is a better tone in many districts. Some of the cities where the manufacturing is of a diversified nature, and where little depends on the automobile business, are having good business. The auto industry has not yet reopened to any great extent, although some of the shops have made a start in a small way, but just now will not commit themselves as to the extent to which they hope to increase the force.

### Reports Improvement

Sales of small tools are improving, but the improvement is coming as the result of two things, viz., hard work and the fact that users of small tools have nothing in stock. One of the dealers told Machinery this week, "We have done more business in small tools this week than we did last month. There were no very large orders, but a lot of small ones. There must be some good buying done as soon as things start to get busy again because none of the shops have anything much on hand. Usually they have stock that will take care of their operations and it is to the interest to keep a good line ahead, especially on sizes that are much used. We look to see a good deal of business inside the next few months."

### The Steel Market

Apart from boiler tubes there is no brisk buying in the steel trade this week. There is always the usual orders to be attended to, but there is nothing apart from this. Some of the manufacturers continue to appeal to the warehouses to relieve their account by taking back certain material they have in stock, and for which they have no immediate use. In many cases this has been placed in stock at a figure above the present market price, and dealers are not inclined to take anything back in the present market.

Some of the independent mills have men over in Canada now looking for business, with a view of getting enough tonnage on their books to start operations. One rather noticeable thing is that a salesman from one of the smaller tube mills was in this district calling on the trade. "Why for the last five years that chap has gone around hardly on speaking terms with us," stated one of the steel trade men to-day, "but now he is quite willing to drop around and talk business with us looking to securing an order."

Most of the steel warehouses do not look for much business for the next few weeks. "As far as we can see the first quarter of the year will be a dull one," was the comment of one dealer. "After that, from what we can gather, there should be much better going."

Pig iron is down from the last quotation, foundry iron being quoted now at $43.64. Buying is not very free now, and users are taking on just such amounts as they consider necessary to get along with.

### May Improve Shortly

The scrap metal market shows nothing on the surface that would lead one to see any improvement, but dealers believe that things are going to get better before long, and the average scrap metal man is not a confirmed optimist. One of the dealers has just returned from a trip through quite a section of United

## POINTS IN WEEK'S MARKETING NOTES

**The new price announced for pig iron in this district is $43.64 per ton for No. 1 foundry iron. Buying for iron is not particularly active at the present time, most firms taking on only what they need for immediate use.**

—

**A representative of the largest scrap metal concern in the country has just made a trip to a district in the United States where considerable scrap from this country is disposed of. He believes that there is going to be an improvement in the scrap metal situation very shortly.**

—

**One dealer in small tools reports that business is much better. In fact he claims that he has done more business in the last week than in a month previously.**

—

**Some manufacturers continue to appeal to warehouses to take back some of the material they have in stock. This is not being done as warehouses generally are trying to reduce their stocks so that they may take advantage of any better buying opportunities that may develop.**

—

**Reports from the New York machine tool market say that there is more inquiries although most of these are for single machines. Makers have so far adhered to their old selling prices.**

—

**Pittsburgh reports that there is more price cutting going on at times, but for the most part each cut represents a single sale and cannot be taken as meaning that the practice of price cutting has become general.**

—

**Stell mills in Chicago district announce reduction in wages of 20 per cent. at two of the largest establishments.**

States where a great deal of scrap metal is usually disposed of. He believes conditions there are going to improve quickly, and there should be a chance, if there is no improvement here, to send Canadian metals across the line. At present Canada is paying more for nearly every grade of scrap material than United States. Yards are still operating on a very low basis.

## NEW YORK LOOKS FOR IMPROVEMENT

**Conditions in General Favor Renewed Trade—No Change Made in the Selling Prices**

NEW YORK, Jan. 20.—While there is no noticeable improvement in machine-tool business, sentiment is somewhat more cheerful as a result of the apparent turning of the tide in the business depression.

Since the first of the year the developments in certain industries, notably textiles, have been of an encouraging nature, and a better tone has been reflected in the security markets, all of which has its effect on sentiment.

Inquiries are slightly greater in number, although mostly for single machines. There is nothing tangible upon which the machine-tool trade can base expectation of a revival in tool buying, but some expect a very gradual improvement from now on. Many manufacturers are still engaged in taking inventories and when these are completed they may give their attention to machine-tool requirements for this year. The demand for used tools, particularly large types, is better.

While there have been a few price reductions by machine-tool manufacturers, the majority have taken no action and probably will not do so for the present. The attitude of the trade is that reductions would not stimulate buying and are not justified, according to present costs of production.

## PRICE REDUCTIONS HAVE BEEN MADE BY MANY INDEPENDENTS

Special to CANADIAN MACHINERY.

PITTSBURGH, January 20.—The iron and steel trade very generally approves Judge Gary's statement made to the newspapers last week. The statement, as is always the case with Judge Gary's utterances, is temperate and at the same time it is hopeful. It is interesting to note that in less than three months Judge Gary will round out 20 years of active service as chairman of the United States Steel Corporation. He does not claim that the steel business has improved of late, but he insists that general sentiment is better and more hopeful. Prices of some commodities must come down farther, he says, the public being in a waiting mood and being ready to take hold when it is convinced that prices are right. Judge Gary does not say that steel prices will not decline from the present level, and probably believes that eventually they will, particularly as costs are going to decrease.

### Production

There has been no material change in the rate of steel production since the first of the year, the rate being slightly over 90 per cent. for the Steel Corporation and about 25 per cent. for the independents, representing in ingots about 21,000,000 tons a year for the corporation and 7,000,000 tons for the independents, or 28,000,000 tons altogether. This is two-thirds the rate at which steel was made during the first nine months of last year, but it is only about 53 per cent. of the capacity. On account of various difficulties, chiefly the insufficiency of rail transportation facilities, steel production during the first nine months of last year averaged only 80 per cent. of capacity.

It will be noted that according to the above estimates the Steel Corporation is producing about three times as much steel as the independents, whereas it does not have more than 44 per cent. of the capacity. The condition is, of course, the aftermath of the divergent price policies pursued in 1920 by the Steel Corporation and independents respectively, the corporation holding its prices down to the Industrial Board schedule of March 21, 1919, while the independents advanced their prices by various amounts, some to the highest figure that could be obtained from anxious buyers for prompt shipment, others to various intermediate levels. Naturally at the windup the Steel Corporation found itself with a well filled order book, while the independents had relatively little on order books, and some of that business was cancelled or suspended, even though eventually the independents marked down the prices in their contracts to the Steel Corporation level.

All this has been well understood, but what is developing now is of particular interest. It might have been thought that when the independents got down to the corporation price level a good bit of the Steel Corporation business would be cancelled, and the independents, by making slight cuts in prices, would be able to get some of that business. The outcome, however, is proving quite the reverse. The corporation has had some cancellations, but it is not of business that is being transferred to independents. On the other hand, some buyers who have not heretofore been customers of the Steel Corporation at all have been making an effort to get on the Steel Corporation's books, feeling that that will be a safe place, in view of th probability that steel will at some futu time become scarce again, whereupon th experiences of 1920 may be repeate though of course in milder form.

### Prices Remain Steady

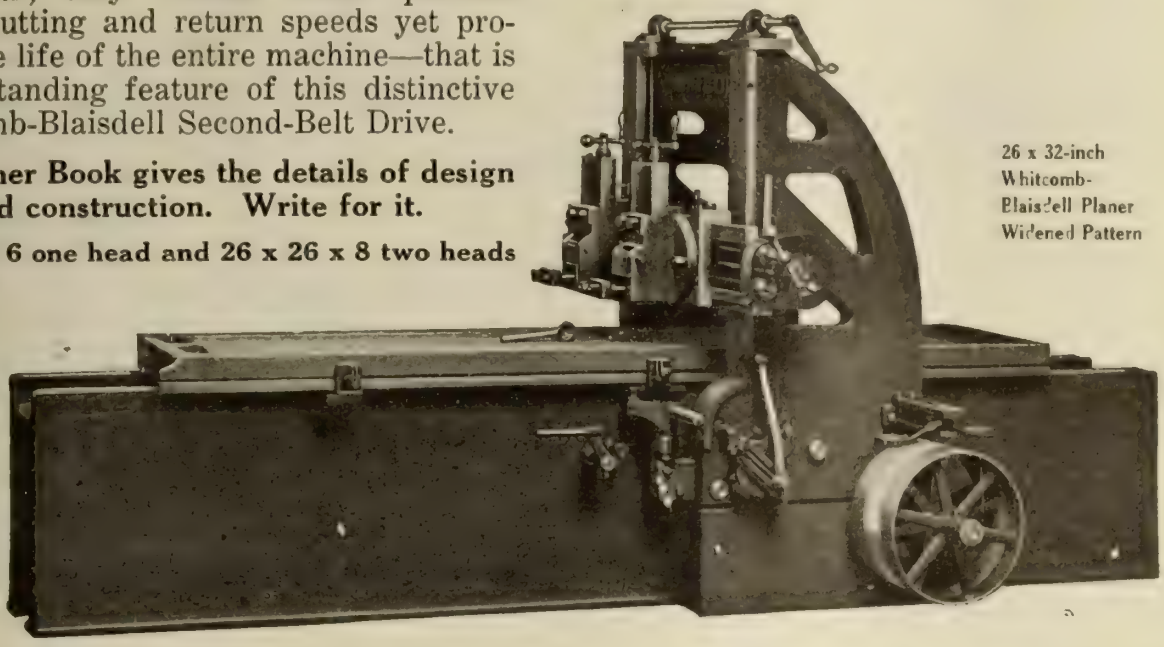
There is scarcely any actually ne business developing, and as a result th independents have no business offere them of sufficient importance to justif their doing much price cutting. Price are only cut, of course, when there is a incentive. Thus the finished steel ma ket may be described as steady, being a the same time very far from active.

No doubt in some lines there is occa sional price cutting, say by from $1 t $3 a ton, but each instance represent a separate case. A cut price sale doe not reduce the market to the lower leve In a regularly declining market that what occurs. A few sales are made a a certain cut, then to effect addition sales the mills have to make fresh cut and so on. There is no such proce now. Eventually, no doubt, this wi come, but there are two pre-requisite a larger volume of new business offere making price cutting worth while, ar a reduction in costs.

### Wages and Costs

The latest reports are that the Inlar Steel Company and the Steel & Tul Company of America, both in the Ch cago district, have cut wages 20 per cen effective January 16. Previously, redu tions had been announced by the Whee ing Steel Corporation, Bethlehem Ste Company, Midvale Steel & Ordnan Company and some minor steel interest There have been no wage reductions consequence in the immediate Pittsburg district or in the Youngstown distric On the whole less than half the indepen ent steel capacity has reduced wage while the Steel Corporation does n seem to have considered the matter ar it is not expected to make any reductio for a long time.

The independents that have not r duced wages are keeping their counse but it is a fair assumption that the attitude is about as follows: A wag reduction at this time would do litt good in reducing costs, when mills a operating so lightly. It would encourag buyers to look for lower prices, or eve demand lower prices. The men wou not accept wage reductions as willing as after a period of idleness, such a they have lately begun to experienc while at the same time the continue decline in the cost of living will help make wage reductions acceptable.



Another consideration of importance this, that there are various methods getting down costs, apart from the mak ing of a horizontal wage reduction, tha should naturally be practised first. Le efficient men can be let go and the mo efficient retained. Bonus rates can b discontinued, men being let go and r

**Pig Iron**

The $33, valley, price on foundry iron has yielded, as it was to be expected it would when actual buying developed, particularly since basic had been voluntarily marked down by furnaces to $30. Several furnaces have sold in lots averaging about 500 tons each at $31.50, valley. They had quoted $33 but buyers would not take hold, and the $31.50 sales were probably made by furnaces accepting a bid at that figure. Nothing has occurred in Bessemer or basic. The market is now quotable at $32 for Bessemer and malleable, $30 for basic and $31.50 for foundry, valley basis.

# CANADIAN WAR MECHANICS ASK CONSIDERATION FOR THEIR CLAIMS

Many Canadian mechanics who went to Britain to work in war shops have appealed to Premier Meighen for relief from the discrimination they have encountered and for the loss they sustained while working in the British shops.

Some of the experiences are set forth as follows:—

When the urgent call for experienced munitions workers came to Canada from Great Britain, the statement sets forth, members of the association responded. A large percentage were married men who entered into the proposal from high patriotic motives, and, forgetful of the financial aspect of the matter, failed to make proper provision for their dependents left behind. These dependents, it is stated, received no benefits under the Patriotic Fund, and, in a number of cases, mechanics returned home after four years' service to find their families destitute.

Believing it would be economy, many of the married mechanics took their families to England with them, at their own expense.

Shortly after arriving, it was learned that British munition workers in shops ten miles or more away from home, received $4.20 a week subsistence allowance. Canadian mechanics, working under British government contract, applied for the allowance, finding wages paid them were insufficient to meet the cost of living.

After some negotiation, the allowance was granted, but only to such men whose families were still in Canada. No subsistence was allowed men with families in England.

**Allege Unfair Pay**

The Canadian mechanics were paid on the basis of pre-war rates for skilled British workers. They received increases as granted to the British workers, but these did not come until 1918, and for at least three years, $10 a week, it was asserted by the delegates, was a common wage for a married man. When the "Dilutee" system was inaugurated, British factories and shipyards were throng-

ed with unskilled women and young men who were allowed to work on the piece work system. The Canadian mechanics were given the task of training these dilutees, and it fell out, in a short time, that many of these new workers were making as high as $15 a day shift. Efforts by the Canadian mechanics to obtain piece work privileges proved fruitless, and it soon became common that the worst student worker in a shop was getting as much or more per day as the skilled mechanic teacher was getting a week.

After the armistice, the statement continues, British munition workers were given benefit under the unemployment insurance plan—to which Canadian mechanics also had paid weekly. The benefit amounted to $6.96 a week for 26 weeks. Canadians were shipped home and given a total amount of $23.75 "resettlement money" to take care of the period of unemployment in Canada.

The statement concludes with a summary of claims, to which Mr. Meighen promised to give close attention at an early meeting of the cabinet.

Here is a synopsis of the claims:—

That the Canadian government give the mechanics status as returned soldiers and eliminate discrimination against them.

That subsistence equal to that paid British munitions workers be paid for the entire period during which it was withheld.

That the same unemployment benefit given British mechanics be accorded Canadians who paid into the insurance fund.

That 50 cents a day for every day of service be awarded each overseas mechanic resident in Canada, toward re-establishment.

That overseas mechanics be brought under the Soldier Settlement scheme.

That repatriation expenses be allowed such as were compelled to return to Canada, before the armistice was signed, through ill-health.

# STEEL OF CANADA SALES FORCE HOLD SESSION IN MONTREAL

THE ninth annual sales conference of the Steel Co. of Canada was held at Montreal on January 13, 14 and 15, the sessions taking place at the Windsor Hotel. The gathering was representative of the entire organization, and a number of the executives and factory heads were also there, including the works manager and superintendents from the plants at Montreal, Brantford, Hamilton, Toronto and Belleville.

The Thursday morning gathering was largely of the get-together order, when the incoming visitors were welcomed by the committee in charge. Mr. Robert Hobson, president of the Steel Co. of Canada, presided at this gathering, assisted by Mr. R. H. McMaster, vice-president, both of them dealing with several matters of interest to the company. The secretary-treasurer, Mr. H. H. Champ, went extensively into figures dealing with the sales of the organization, and also with the exchange rate during the year 1920, pointing out that the average against Canadian money during that period had been 13 per cent. One point was brought out that was of special interest, and which by the way reflected no small credit on the collection department and the sales force, viz., that the losses through non-payments of accounts had amounted to only a small fraction of one per cent.

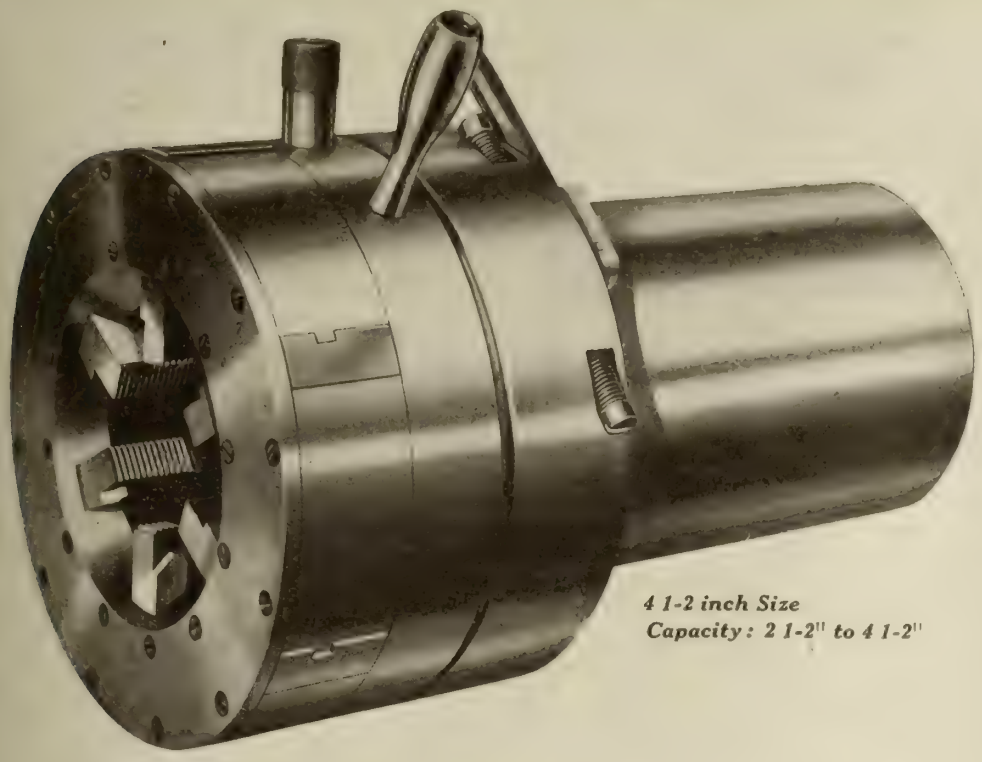
Mr. Lloyd Harris, a director of the company, was also one of the speakers at this session, having only a day or so before attended a meeting of the automobile manufacturers in Detroit, where the whole position had been thoroughly discussed. Mr. Harris made it clear that there was need for more aggressive selling now than for some time past. For a long time everything had been in favor of the seller, the real salesmanship had been allowed to lapse in many cases. The market was in favor of the buyer now, and salesmen ought to adjust themselves to these changed conditions. The meeting in Detroit had felt that things were definitely on the mend now, although the start might have to be made in a small way, but a better buying movement was looked for, and it should take on definite form early in April, and perhaps in some measure before.

The sales conferences themselves were presided over by Mr. H. T. Diplock, eastern sales manager, Montreal, and Mr. George Spence, western sales manager, Hamilton, able assistance being given by Mr. D. J. Black, assistant sales manager at Montreal, and Mr. Charles E. Harrison, assistant sales manager at Hamilton. Reports given by a number of the men from various parts of the Dominion dealt with many phases of trade and problems of salesmanship. The consensus of opinion was that trade was going to be better early in the year. Stocks in nearly every centre are low, and manufacturing concerns are not putting in their accustomed supplies of raw material, so when business does start to move there will be purchasing done on a fairly good basis.

Some of those who are accustomed to be present at the sales conferences, but who were not able to be there this year, through various causes, were Charles S. Wilcox, chairman of the Board of Directors, Cyrus A. Birge, one of the directors, George A. Simpson, special representative, Hamilton, Thomas Moore, assistant sales manager, Hamilton, and D. B. McCoy, of Vancouver.

The annual banquet at the Canada Club proved to be a thoroughly enjoyable affair, and the entire company stands ready to vote Mr. Hobson the one and only chairman for such an occasion. The toast to "our officers" was proposed by J. Orr Callaghan, works manager of the Canada Works, Hamilton, the response being given by Mr. Robert Hobson, president, Mr. R. H. McMaster, and Mr. H. H. Champ. "Our works," was responded to by Mr. Jaquays, works managed at Montreal, and Mr. R. G. Wells, works manager at Hamilton, also superintendents McEwen and John L. Smith of Hamilton, and Flaherty and Johnson of Montreal. "The Sales Organization" drew responses from Messrs. Spence and Diplock, sales managers of west and east respectively, Fred Perego and Stuart Kell. One of the most impressive incidents of the gathering was the response by Mr. Fesserton, of Montreal, to the toast of the "Visitors." Mr. Fesserton, who has retired from active life, was for fifty years connected with the Steel Co. of Canada and its predecessor, the Montreal Rolling Mills, which was taken in at the time of the amalgamation Mr. Hobson issued a special invitation to him to be present at the banquet in Hamton next year to the sales force.

The committee in charge of the conference and banquet earned the thanks of the whole organization. They attended to every detail and left nothing undone that would make the affair a success. They were Messrs. H. T. Diplock, J. D. Black, A. Y. Paxton, S. N. Colcomb and E. M. Russell. About 150 attended the conference.



### The Steel Poet Sings

The Steel Co. of Canada harbors in its Montreal branch a bit of a poet, in the person of H. E. Skeats. On top of the menu card used at the banquet of the sales organization were several verses from Mr. Skeat's quill.

Looking back over the restricted diets of war years the Montrealer lifts his voice and chants thusly:—

Good evening, gentlemen—take your seats,
And run your eye o'er this list of eats,
Food censors have vanished in ambient air,
So hew your way through the bill of fare,
Nor trouble yourselves with the awful thought
That you're putting away what you didn't ought!

I suppose you remember the days gone by
When on bacon, and butter, and beef you were shy,
When you dare not consume a succulent steak!
For fear that a Food Commandment you'd break
When the grub you ate, as it sank to rest,
Seemed to your sensitive souls to protest
That you had no right to devour, by gee,
The food that should nourish a refugee!

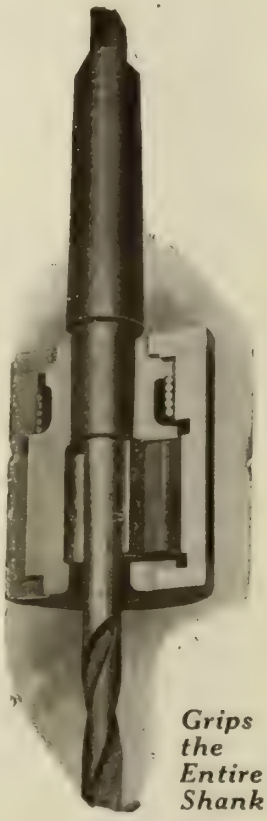
## Wahlstrom Automatic Tapping Attachment

Tap breakage becomes a thing of the past when you use the Wahlstrom Tapping Attachment. The tap is prevented from jamming in the hole by keeping the lands free from chips. The chips are freed by an oscillating motion which duplicates the simple to-and-fro motion of hand tapping. For tapping in soft materials the oscillating motion can be changed to a continuous revolution.

The Wahlstrom fits any drill press. Made in two sizes. No. 1 takes taps of all sizes from 5-40 to ½ inch; No. 2 takes taps from ¼ inch to ¾ inch.



## Wahlstrom Chuck

### *Holds Tools with or without Tangs*

The instant-acting jaws of the Wahlstrom close on the entire shank with a grip which becomes firmer and firmer as the resistance of the tool increases. The clutch positively cannot slip and the jaws never break or mark a tool.

Two seconds is all you need with a Wahlstrom to change from drilling to reaming, counterboring, or tapping. Don't stop the spindle—just grasp the chuck with one hand and change tools.

Made in two different styles. One style holds Nos. 1, 2, or 3 Morse Taper Shank Drills—with or without a tang. The other style is made in three sizes, which hold all sizes of straight-shank tools from ¼ to 1 inch.

*Grips the Entire Shank*

# The Week's Events in Montreal Industry

Lieut.-Col. Gardiner of Robt. Gardiner & Sons, Montreal, who has been confined to his home for the past three weeks by illness, is now reported to be progressing favorably and it is hoped that he will soon be able to make his usual appearance at the office.

---

Following the fire that occurred at the foundry of W. R. Cuthbert and Company, 41 Duke street, last week, it has been announced that immediate plans have been made for the reconstruction of the building and the acquiring of equipment and machinery that will make this plant equal to any in this locality. No time will be lost in clearing away the debris and starting work on the new foundry.

---

J. W. Norcross, president of the Canada Steamships, who has been in England and Europe since October last, with the exception of one week that he spent in Montreal, is expected back about the end of February or the beginning of March, at which time it is estimated that there will be further developments to announce in connection with the Canada Steamships' part in the proposed British Empire Steel Corporation merger.

---

It has been stated that final arrangements have been made for the commencement of work in connection with the large hotel to be constructed by the Mount Royal Hotel Company, on the site of the old Peel Street barracks, near the corner of Peel and St. Catherine streets. The cost of the structure when completed will be in the neighborhood of $9,000,000, and it is anticipated that actual operations will be started by the first of April.

---

The Sheffield Engineering Supplies, Limited, formerly Forrest, Jackson and Forrest, of 230 Craig street west, Montreal, have acquired the Canadian selling agency for Michael and Joseph Wing Ltd., of Sheffield, England. This firm are large manufacturers of commercial iron and steel products, specializing in bar stocks for a wide and varied range of purposes. The lines include the best grades of carbon, tool, crucible and high speed steels.

---

The Shaughnessy shield for Eastern Canada for first-aid work in connection with the St. John Ambulance Association, was, last week, presented to the police team of the C. P. R. of Montreal. The presentation was made by Lord Shaughnessy, who emphasized the value of such training, especially for those associated with railroad work. The shields and medals have been won several times by C. P. R. teams. The team was in charge of Inspector Logan, and the members were: Capt. Wilfred Mansell, Acting Sergeant George Curtis, and Constables Arthur Hart, Percival Hawley and Jesse Holmes.

---

Owing to the abnormal rise in the level of the River St. Lawrence during the past week, it has been found necessary to close some of the sewer outlets, and pump the sewage through the special outlets, as there is danger of flooding by using the regular channels when the water is exceptionally high as it is at present. Officials of the city state that it is unusual to operate the pumps in January although it is frequently done during the month of December. The cause of the present rise is the blocking of the ice at the foot of the island, but precautions taken will avoid any serious flooding to streets and cellars in the vicinity.

---

W. D. Robb, operating vice-president of the Grand Trunk Railway, has announced the appointment of G. A. Kell, to the position of safety engineer of the system, with headquarters at Montreal. Mr. Kell has been associated with the motive power department of the Grand Trunk since his boyhood, acting in the capacity of travelling engineer for the past ten years, and is thoroughly conversant with the safety requirements of the entire system, and a large part of his new duties will be the supervision of the "Safety First" campaign among the railway employees.

---

Canadian Northern officials at Moncton, N.B., have been instructed to lift the embargo that has existed against the steel company, at Sydney, for the past few weeks. It is not known whether this relief is of a permanent character or only a temporary one, but the advices state that the freight will be accepted as formerly. In this connection it may be stated that reports from Sydney indicate an early settlement of the trouble between the freight handlers of the Dominion Iron and Steel Company and the officials is looked for. Owing to threatened action on the part of the Railroad Brotherhood, the situation became so serious that the steel company refrained to call upon the railway company to accept material for shipment. The atmosphere is now clearing and it is hoped that things will again be normal before the close of the month.

---

At the regular monthly meeting of the Canadian Railway Club, held in the Windsor Hotel on the night of January 11, a highly interesting paper was read by Capt. A. H. Kendall, M. C., O. C. 58th Broad Gague Operating Company, C.E.F. (now master mechanic of the C.P.R. at Montreal.) The title of the paper was "Operating Broad Gauge Railways in France Under War Conditions," and the large number of members attending showed quite clearly, the extreme interest taken in this interesting and instructive paper. The annual dinner of the Railway Club will be held in the Windsor Hotel on the night of the 29th of January, when it is expected that W. H. Taft, ex-president of the United States, will be the principal speaker. The Hon. F. B. Carvell, chairman of the Board of Railway Commissioners, has accepted the invitation to respond to the toast of the railways. Stephen Leacock will be on hand to reply to the toast of our guests.

---

A movement is on foot in certain quarters to secure the Foundrymen's Convention for Canada next year. The matter was discussed at the last convention in Columbus and Montreal mentioned, and as is usual when the name of a city is put forward as a possible meeting place for some future convention, the suggestion was favorably received at the time. Mayor Martin of Montreal has been approached on the subject and has promised his hearty co-operation, and it is understood that he is taking the matter up with the Prime Minister personally, to arrange for the elimination of red tape on custom duties etc., in getting American exhibits over the border. The question of securing a suitable hall for exhibition purposes is also under consideration. The Arena has been suggested but it is probably too small for the purpose. It is thought that the drill hall on Craig street can offer the largest amount of floor space available in the city for the necessary exhibit of foundry equipment. We understand that Mayor Martin, once these difficulties have been removed, will extend an official invitation in the name of the city of Montreal to the officers of the Foundryman's Association in Chicago. The possibility of the Convention being held in Montreal has aroused considerable interest, and all-around approval in Canadian foundry circles, and they promise to extend the good hand of fellowship to their American brothers if the convention is held in their city and further assure them that they will find many of their compatriots here, if one can judge by what occurred last summer when the streets of Montreal were filled with visiting American tourists and convention delegates drawn there by reasons which are said to be not entirely unconnected with the 18th Amendment to the Constitution of the United States.

**Unique Order.**—Eleven vessels, ranging in size from gas boats to big stern wheelers over 200 feet in length, with a total value of well over $200,000, will be built in Vancouver for the Hudson's Bay Company for operation on the Mackenzie River during the coming spring and summer months, according to information given by an official of the company who is making arrangements for the commencement of the work.

## Engineering

The H. Mueller Mfg. Co., Sarnia, are contemplating a large extension to their plant.

The erection of a steam heating plant is planned by the Chatham Steam Heating Co.

Erection of a warehouse is being planned at Regina, Sask., by the McColl Bros., Ltd., Toronto.

The Dyrob-Steel Co., Orillia, Ont., has decided to proceed at once with the erection of a factory.

Arrangements are being made to enlarge the plant of the Tuttle-Bailey Mfg. Co., of Bridgeburg.

The London Concrete Machinery Co., London, Ont., are erecting a $50,000 addition to their factory.

The erection of a paper mill is being planned by the Provincial Paper Mills, Ltd., Port Arthur, Ont.

A storage shed will be built by the Warren Bituminous Paving Co., Ltd., 19 Melinda Street, Toronto.

A new memorial hospital is to be erected in Whitby next year on the site of the Perry Castle Block.

Plans are being made by the Canada Cement Co. to erect a large office building on Phillips Square, Montreal.

The Government Telephone Commission, Ochre River, Man., are about to erect a telephone exchange building.

The Transparent Rubber Co., 1555 Danforth Ave., Toronto, was gutted by fire on Saturday, January 15. The loss is estimated at $24,000.

The Bell Telephone Co. plans to expend $10,424,412 this year on new plants, including $3,535,518 in Toronto, $228,200 in Hamilton and $453,000 in Ottawa.

Plans are being made by the General Public Hospital Commissioners at St. John, N.B., to alter and build an addition to the hospital at a cost of $500,000.

The Brantford Computing Scales, Ltd., Brantford, Ont., have erected a new factory with foundry attached. Operation will begin in about two months' time.

The Corbet Foundry & Machine Co., 1064 First Ave. West, Owen Sound, Ont., intend enlarging their plant by an addition to cost $25,000. Tenders will be called in the spring.

The plant of the Woodstock Worsted Knitting Co. has been acquired by the American Ironing Board Co. for a Canadian branch. A twelve months' lease has been taken with the option to buy at the end of that time.

J. R. Royer, 118 Murray Street, has been awarded the general contract for the erection of three-story factory for Goupil Ltee, 9 Alexandre Street, Sherbrooke, Que., at a cost of $30,000.

New tenders will be called in the spring by F. J. Wolfe, district representative of the Imperial Oil Co., for erection of warehouse, garage and stables at Riviere du Loup, Que.

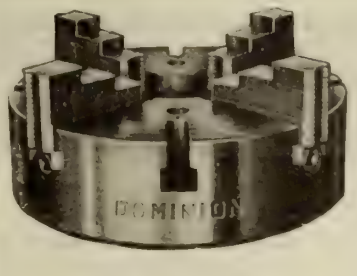
The general contract for the erection of a factory costing $20,000 for the Dominion Canners, Ltd., Niagara Falls, has been awarded to J. D. Nichols, 116 Sumner Street.

Preliminary operations for the erection of the new station, train shed and viaduct for St. John, N.B., for the Canadian National Railways have been recently commenced.

S. R. Cound, general manager of the Baldwin Canadian Steel Corporation, left on January 17 for New York en route to England for three months' leave. The departure of the general manager follows close upon the first production of tin plate in the big plant. Mr. Cound has been devoting his energies to this work for some time.

## Trade Gossip

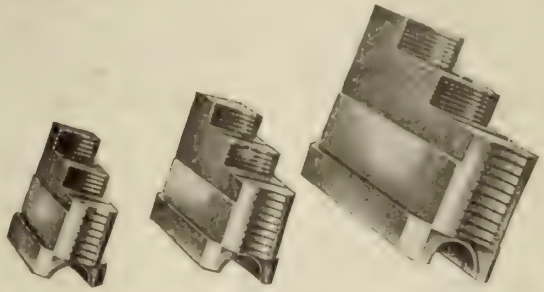
**Morden Retires?**—The retirement of Col. W. Grant Morden, M.P., from the nominal position of chairman of the board of directors of the British Empire Steel Corporation will, it is expected, shortly be announced by Roy M. Wolvin, president of the Dominion Steel Corporation, who went to England recently with D. H. McDougall, president of the Nova Scotia Steel & Coal Corporation, in connection with the merger reported to have dwindled down to these two concerns. It is stated, in fact, that Col. Morden's connection ceased some time ago, although there has been no official confirmation of this.



## Personals

I. Swales has been appointed to the position of general manager of the Chapman Double Ball Bearing Co., Ltd., Toronto.

Thos. Southworth, managing director of the Deloro Smelting & Refining Co., Ltd., together with F. A. Bapty, secretary-treasurer of the same company, spent several days this week in New York city on company business.



E. W. Sawyer has resigned his position as general manager of the Dominion Abrasive Co., Ltd., Mimico. Mr. Sawyer has held the position since the inception of this concern in 1920. Their plant was also located in New Toronto.

**Steel Tenders Wanted.**—W. A. McLean, Deputy Minister of Highways for Ontario, is advertising for tenders for reinforcing steel. Sealed tenders, marked "Tender for Contract No. 309," will be received by him until 12 o'clock noon on Tuesday, February 1st, 1921, for the supply of approximately 250 tons of round steel, reinforcing bars for culverts, and of expanded metal for bridge floors. Delivery will be required prior to May 1st, 1921. Specifications may be seen on and after Friday, January 14th, 1921, at the office of Mr. McLean, Parliament Buildings, Toronto.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

The Jaws Are Extra Strong

THEY are drop forgings, made of best quality steel, heat-treated and hardened. The threaded portion of jaws form a half nut for the setting-up screws. Have stood the test of heavy duty work in our own shops where accuracy was the only accepted standard.

## MADE ADVANCES AFTER CLOSE STUDY

**John J. Main Was Inventor of Note—Passed Away in Toronto Recently**

John J. Main, inventor of the Heine boiler, and one of the outstanding figures in Canadian foundry circles, died at his home, 40 Prince Arthur Avenue. He had been ill a long time, and death folloewd a stroke, the fifth of its kind.

Mr. Main was born on the island of Jersey 70 years ago. He came to Canada as a young man, and for years worked at his trade as a boilermaker. It was the invention of the Heine boiler which gave him his real start in life. He became connected with the Polson Iron Works, rose rapidly, and when he retired three or four years ago was vice-president and general manager.

During the war Mr. Main served on the Imperial Munitions Board. Free of charge, he turned over to the military authorities his patents on boilers fed with crude oil, which were used extensively in many branches of the service.

Mr. Main was president of the Canadian Incinerator Company, president of the Policy Holders' Mutual Life Insurance Company, and a director of the Dominion Radiator Company. He was superintendent of the Doty Engine Company, John Inglis & Sons and the Bertram Engine Works at various times during his career.

## WILL FIGHT THE DECREASED WAGE

**Twenty Per Cent. Reduction Is Cause of Trouble in the Sydney Field**

That they will fight by every legitimate means in their power the 20 per cent. wage reduction ordered by the Dominion Iron & Steel Corporation was the decision reached at a mass meeting of Steel Workers' Union, Sydney, N.S. Speaker after Speaker took the floor and declared that there was nothing in either the cost or price of steel or in the trend of the cost of living to justify the drastic wage cut proposed by the Steel Corporation.

An effort will first be made, it is said, to induce the company to change its announced purpose of making the 20 per cent. cut, but if negotiations in this direction fail, then an appeal will be made direct to the Federal Government.

1—10" Burke Sensitive, bench type (new).
20" "Sibley" Champions, Rockwell, and Silvers (new and used).
1—36" C.M.C. Heavy Duty (used).
1—3-spindle 20" Silver Gang Drill (used).
1—4-spindle W. & R. Sensitive (used).
A number of smaller sizes in bench and column type.

**BORING MACHINES**

1—66" Bement-Niles Vertical, 2 head, 24" under rail (used).
1—Universal No. 2½, Horizontal, table 42" x 22" (used).
1—Bullard "New Era" 36", complete equipment (new).

**GRINDERS**

1—"Landis" No. 4 Universal (used).
1—"Landis" Plain, self contained 36" x 12" (used).
1—"Norton" Plain, No. 434 (used).
1—"Fitchburg" Cylindrical, 8" x 36" (new).
Several "Globe," "Stevens," "LeBlond" and "Cincinnati" Cutter Grinders (new and used).

**SHAPERS**

1—14" "Mackenzie" B.G. Crank Shaper (used).
1—16" "Rae" B.G. Crank Shaper (used).
1—24" "MacGregor G" B.G. Crank Shaper (used).

**LATHES**

1—7" Cataract Precision (used and new).
1—12" x 8' "LeBlond" Tool Room (used).
1—16" x 6' "Reed" (used).
1—18" x 8' "Rae" Q.C.G. (new and used).
1—24" x 10' "Milwaukee" (new).
1—30" x 12' "Blaisdell" (used).

**GAP LATHES**

1—12" x 17½" x 6' Perfect (used).
1—20" x 38" x 12' C.M.C. (used).
1—21" x 30" x 7' South Bend (used).
1—22" x 40" x 16' McDougall (used).
1—38" x 54" x 12' Bertram (used).

**TURRET LATHES**

No. 4 Millhollands, capacity 1⅝" (used).
Several Oliver & Davis Turrets, various capacities (used).

**PLANERS**

1—42" x 42" x 20' Putnam, 1 head (used).
1—30" x 30" x 10' Pond, 1 head (used).
1—24" x 24" x 6' Powell, 1 head (new).

**MILLING MACHINES**

1—Whitney Hand Miller, 18" x 6" table (used).
1—Briggs High Duty Type "A," 22" Traverse (new).
1—Briggs High Duty Type "B," "42" Traverse (new).

**POWER HACK SAWS**

1—No. 10 Racine 8" x 8" cap. (new).
1—Peerless 6" x 6" cap. (used).
1—No. 7 Watkins 9" cap. 18" blade (used).

**MISCELLANEOUS**

1—Arbor Press No. 4 "Greenard" (new).
1—Riveting Machine No. 80-B, "Grant" (new).
1—Riveting Machine No. 81-A, "Grant" (used).
1—High Speed Hammer No. 3-A (used).
1—Rotary Bevel Shear, "Lennox," 1" cap. (new).

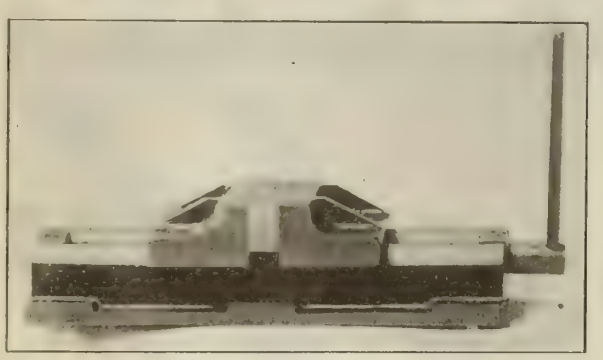
# IMCO TOOLS

## Speed!

A sudden, deafening roar; a quick rush of air, and he is by again! Speed!



How slight a turn of the steering wheel—how slight an imperfection in the construction of the car, would throw him off the track, a burning mass of twisted, white hot metal!

Makers of good cars use "Imco" Tools in their construction. Experience has taught them that "Imco" is the sure way of getting precision cutting.

# SIDNEY

"Sidney for Service"

## Heavy Duty Engine Lathes

### Noted for Their Power and Rigidity

One of the outstanding features of the Sidney is the manner in which it takes deep cuts through tough metals. Clean cuts without chatter, without pause. The Sidney is so designed that rigidity is maintained under severe conditions, and, in normal service.

The 25-inch Heavy Duty Quick Change Sidney here shown is the last word in lathe construction. Every improvement will be found in this, the latest model. Bed lengths available are: 10, 12, 14, 16, 18 and 20 feet. 27-inch swing design can also be supplied in these lengths.

The specific details of the Sidney are given in our new Bulletin. Write for your copy to-day.

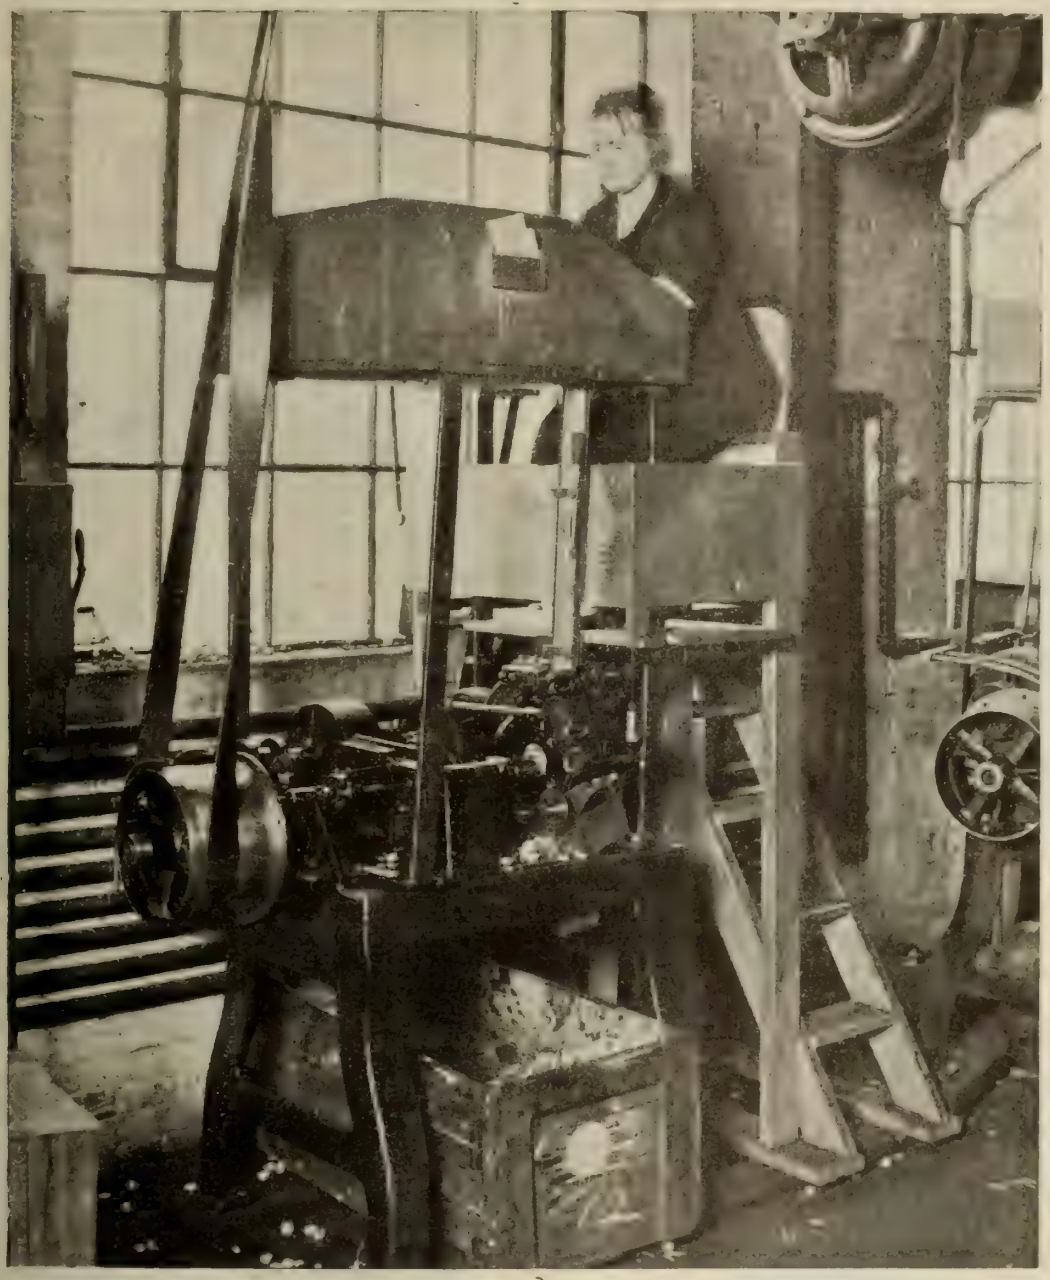
# Snagging on a Norton

What the foundryman needs for rough work like snagging is a sturdy floor stand which can resist the vibrations set up by the grinding wheel.

The Norton floor stand has this sturdiness combined with points of safety and adaptability for foundry grinding.

The operator is not put to any strain. Work-rests of ample dimensions relieve him of holding the work.



With a Norton wheel the working combination is ideal. "Alundum" for materials of high tensile strength, all kinds of steel. "Crystolon" for cast iron, bronze, brass and aluminum.

# Prevent Idle Time
## of Men and Machines

By placing Bowser Lubricating Oil Cabinets in departments where oil is used.

There is no going back and forth to the oil room, no spilling, no wasted oil, no fire risk from the oil storage.

## Save the Oil

The oil supply can be stored and handled as systematically as raw materials or finished parts—income checked, distribution measured, charged and recorded.

*Write for literature, explaining why and how Bowser Systems pay for themselves, many times over in saving of oils and labor.*

# Strong Chucks—

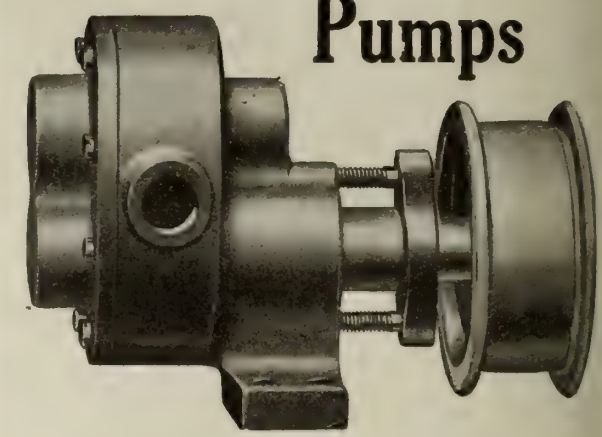
That truly describes Skinner Steel Body Independent Lathe Chucks. They are not only strong and powerful, but wonderfully accurate. The

4-Jaw Independent Chuck, Steel Body, for Heavy Duty

## SKINNER Steel Body Independent Lathe Chuck

is a single steel casting of great strength, well proportioned and accurately finished. Face is graduated accurately in inches. Screws and bearings are made of the toughest steel to withstand abnormally hard wear.

The dependability of Skinner Steel Body Independent Lathe Chucks is conclusively proved by the fact that not one has ever been known to break in service—and we have been making them for many years.



*Write for catalogue and illustrated literature.*

# TRAHERN Circulating Pumps

## *Long, Efficient Life*

We guarantee that Trahern Rotary Geared Lubricating Pumps will not lose their prime when correctly installed. Also that they will deliver a much larger supply of coolant than a centrifugal pump operating at the same rate of speed. This low speed of Trahern Pumps means a more positive flow of lubricant and insures longer life.

**Write for our Bulletin 44. It explains in detail.**

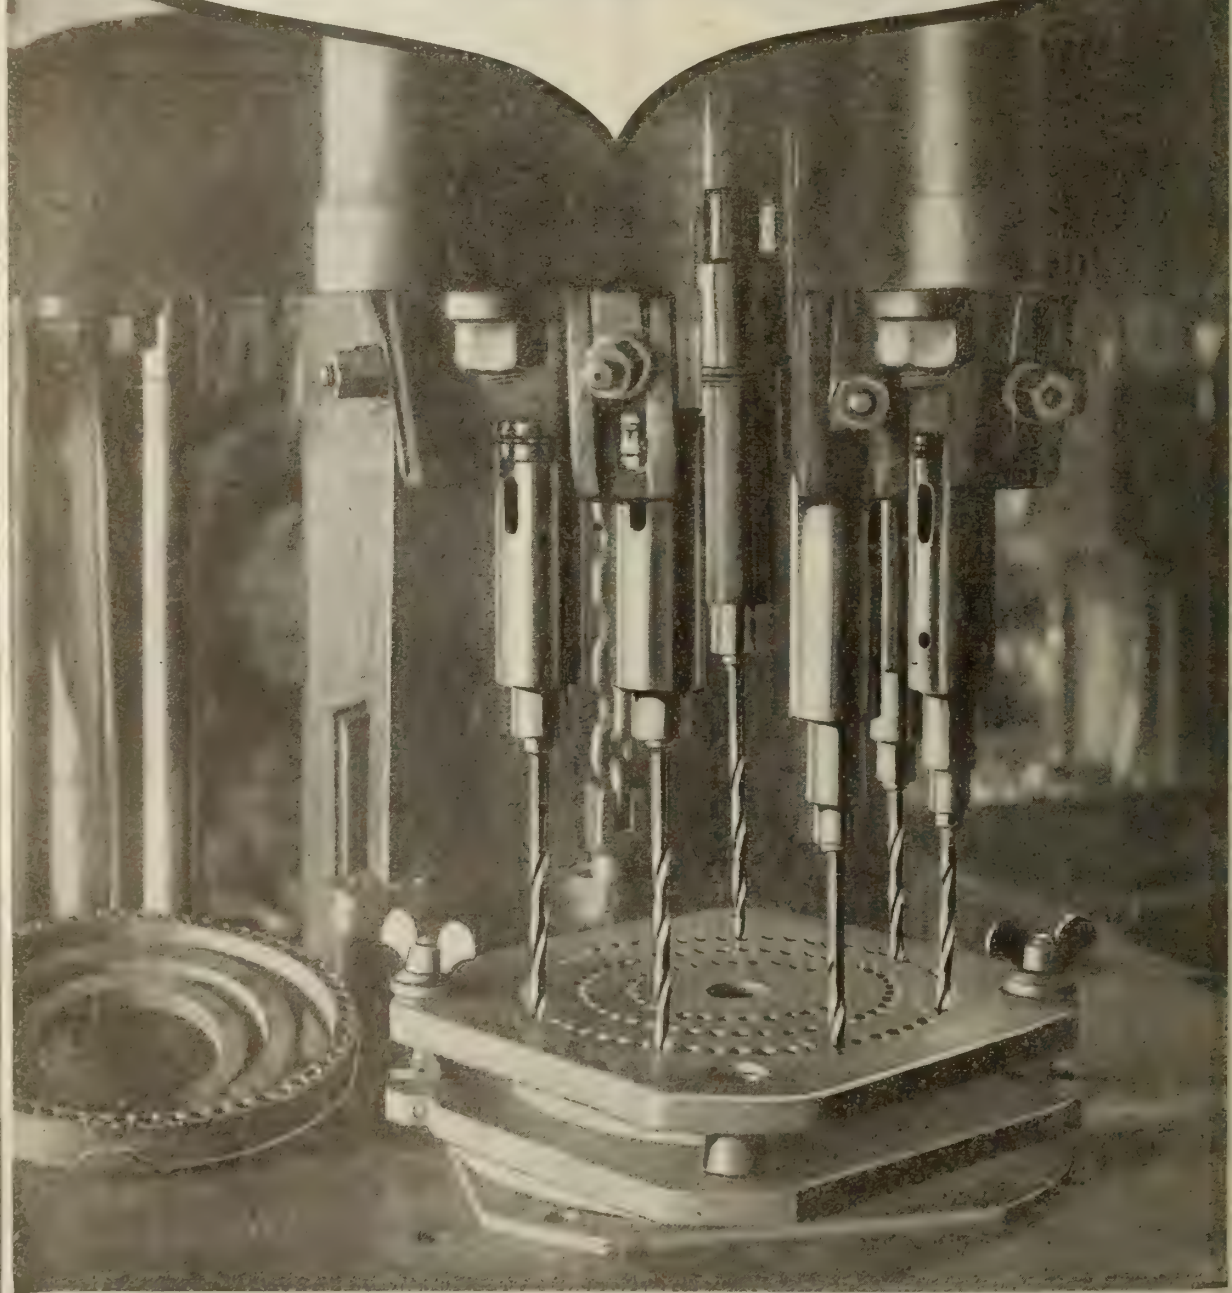
NATCO NATCO

# Drilling 285 Holes in Copper Rotor Rings Every Hour

"A big time-saver," says the U.S. Electrical Mfg. Co. of Los Angeles. Fifty-seven 17 64 inch holes are drilled in each ring; five rings every hour.



This time-saving feature is used on NATCO Multi-Drillers exclusively. The speed of every spindle is independent of the speed of any other spindle and may be changed at the will of the operator to approximately the correct speed required for the size and type of tool being used. All spindles not in use are thrown into neutral, saving wear and power.

Manufacturers who have use for or are contemplating the installation of Multiple Spindle Drilling Machines should give careful consideration to our Independent Drill Speeds a NATCO Patented Feature—One Nut Adjustable Spindle, and guaranteed Universal Joints, also exclusive features which make the NATCO the most economical Multi-Driller on the market.

## THE NATIONAL AUTOMATIC TOOL COMPANY

RICHMOND, INDIANA, U.S.A.

*If what you need is not advertised, consult our Buyers' Directory and write advertisers listed under proper heading.*

# MILWAUKEE MILLING MACHINES

## WHAT IS NECESSARY TO DO THIS JOB?

THE scientific construction of Milwaukee Vertical Milling Machines, with correct distribution of the metal to the column, knee, saddle and table, forms a harmonious unit. The spindle is non-adjustable except for wear, the knee alone being adjustable. This rigid construction gives these machines a degree of strength and power that enables them to efficiently handle the most difficult milling jobs.

### A good, rugged machine with abundant power

The operation shown above is but one of the severe tests to which Milwaukee Milling Machines are constantly put. Four cutters, 2½" wide x 3" diameter, ½" wide x 3⅝" diameter, 7-16" wide x 3⅝" diameter, ⅝" wide x 4⅜" diameter remove ⅛", 1-16", 1-16" stock and cut a slot ⅝" deep out of solid metal, respectively. The length of each cut is 6". The floor-to-floor rate for each piece is 5½ minutes. This work is done with the aid of the rotary table. In order to show the depth of the cuts, part of the casting has been milled and then the cutter was moved back to show this milled section. The balance of the segment is still in the rough.

Milwaukee Milling Machines possess exceptional ruggedness, abundant power and accuracy, making them capable of performing milling jobs of this kind with ease and rapidity. They assure milling satisfaction under all conditions.

# THE K-T FOUNDRY GALT, ONT.

TRADE K-T MARK

## Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

## If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

***We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.***

# End This Extravagance, Says Mackenzie King in MACLEAN'S

**"There is the greatest need for an end to extravagance, and for the exercise of the strictest economy in the administration of public affairs," says W. L. Mackenzie King in the January 15th issue of MACLEAN'S.**

HE adds, further: "The first aim of the Liberal party in Canada to-day is to bring about such co-operation and co-ordination of effort among men and women of liberal aims"—(a small "l" please note)—"and aspirations as will ensure defeat of the combined forces of a reactionary Government, and make possible, in matters of Government, the re-assertion and ultimate triumph of liberal" — (still a small "l")—"principles and policies."

**Is This a Message to Mr. Crerar?**
**Is This a Plea for Union of Farmers and Liberals?**

## Other Big Features in January 15th MACLEAN'S

***There are fifteen other big feature articles, serials, short fiction and regular departments. These include:***

**"The Human Speedometer"**
By Charles Christopher Jenkins.
The story of a Canadian who "times" race-horses as a profession.

**"The Hat"** By Frederick Niven.
A vivid word-picture of a feature of our West which strikes this war correspondent.

**"My Flirtation Ends"**
By Mrs. "Margot" Asquith.
Wife of former Premier of Great Britain tells how her eight years' dalliance with Peter ends.

**"Our Lost Immigrants"** By Miss Agnes C. Laut.
She tells some cold, hard facts, and explains why hundreds of thousands left Canada.

**"Scarlet and Gold"**
By Colonel George Ham.
Who gives here a few chapters from the romantic history of the Royal North West Mounted Police in earlier days.

**"Paying the Doctor to Keep You Well"**
By Ethel M. Chapman.
A worth-while and timely article, depicting the work of the Life Protective Association.

**"A Canadian Child Poet"**
A little bit about twelve-year-old Miss Rae Maltby Verrill, of British Columbia, whose work seems to show promising talent.

### Interesting Fiction

**"The Big Time Man"**
By C. W. Stephens.
A bottling-business romance.

**"The Act of God"**
By Beatrice Heron-Maxwell.
A near-murderer's escape.

**"Jane Ann's Rival, Mabel"**
By Archie McKishnie.
A Lenix Ballister episode.

**"The City of Peril"**
By Arthur Stringer.
A romantic, Bolshevistic serial.

### Review of Reviews

***The Cream of the World's Literature:***

**"The Dreamer in the Kremlin."**—H. G. Wells.

**"Chaplin Prey to 'Blues'."**—Benjamin de Casseres.

**"Which Labor Policy?"**—Wm. B. Dickson.

**"How Militarist is Japan?"**—Quarterly Review.

**"Trapping an Elephant Herd."**—Charles Mayer.

**"Why Not Tax Bromides?"**—Henry Arthur Jones.

**"Trotzky, a Human Dynamo."**—Francis McCullagh.

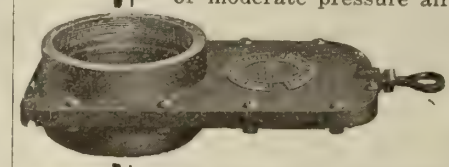
80 H.P. Morse Drive to Rolls, reverses direction every 45 seconds

# STRENGTH



Strength is a very essential quality in a wrench, but it does not depend entirely upon bulk or weight of metal. The strength and long-lasting qualities of Armstrong Wrenches are the result of skilled combination of the Best Steel, Expert Design, Accurate Machining, and Heat Treatment. All kinds and sizes.

Write for free catalogue.

**Armstrong Bros. Tool Co.**
"The Tool Holder People"
335 N. Francisco Ave., Chicago, U. S. A.

# New Air-Tight Blast Gates

will help you maintain the safety, economy and efficiency so essential in the operation of furnaces and other appliances using low or moderate pressure air.

THEY ARE SAFE— because they are ruggedly built of only a few simple parts; the blade stays fixed in any position and by a slight pull of the handle is easily adjusted to give the blast desired.

THEY ARE ECONOMICAL—because the initial cost is small; the simple construction eliminates wear and tear.

THEY ARE EFFICIENT—because careful machining makes them AIR-TIGHT; they afford the full area of the blast pipe, in striking contrast to a stop cock; they are quick in operation; they can be placed in any position.

***In short, these New Air-Tight Blast Gates possess all the advantages of stop cocks and valves, and have special features that tend for greater usefulness and economy.***

SIZES 2" TO 16"

HENDEY

# Hendey Lathes Speed Up Rush Work

HENDEY Lathes are setting new records on all kinds of rush lathe work.

The above 24-inch HENDEY Engine Lathe is machining a valve seat. This operation it completed with the usual HENDEY speed and accuracy, in two hours.

For speed, for accuracy, for durability and low maintenance there is no better lathe than the HENDEY. The satisfaction they are rendering their users everywhere can be duplicated on *your* work.

Foss QUALITY Foss SERVICE Foss

# The C.M.C. Motor Driven All Geared Head Engine Lathe

*Sizes 16" to 42"*

This Lathe does not depend on belts or line shafts to keep it going and has, therefore, many distinct advantages over the belt-driven machine.

It may be run when the rest of the plant is idle. Remember that odd job you wanted to finish after hours and couldn't do it without running the whole shop?

It may be placed in the position most suitable for the work required to be done, regardless of shafting or belting arrangements.

Eighteen speeds are supplied from thirteen gears, making it very simple to operate.

*Full details and prices on request.*

## WHEREVER THERE IS A PAYROLL There Should be INTERNATIONALS

ACCURACY is the first requirement of timekeeping and payroll systems. The clearly printed records produced by International Time Recorders provide a reliable means of obtaining that accuracy.

Wherever there is a payroll there should be Internationals.

# International Time Recorders

Are manufactured in electrically and spring driven models designed to meet every timekeeping and cost keeping requirement of any size and kind of business.

Through unfailing accuracy and fairness Internationals put the interests of both employer and employees on a basis of guaranteed protection and profitable harmony. May we tell you about the adaptability of Internationals to your specific needs?

P & W

# Pratt & Whitney Taps

**"With the 'Con-eccentric' Land"**

P & W Taps are **good** taps—easily the best where accuracy and high speed are essential. They cost more to buy, but less to use than others.

If you're doing work that calls for big production and for unusual precision, give them a trial. You'll be back for more when you see them prove themselves.

The "con-eccentric" land—the special feature of Pratt & Whitney Taps, permits sharpening on face of the cutting edge without affecting size. It lengthens life and assures accuracy hitherto thought impossible in a commercial tool.

# *Little Giant—the Adaptable Electric Drill*

GOOD Drills, like good men, perform dependable work and require little attention.

Six years ago the Little Giant Electric Drills illustrated, started cutting down production costs in a large Pittsburgh Steel Plant—and they are still hard at it! (The special buggies upon which these Little Giants are mounted, are not manufactured by this Company, but show the adaptability of Little Giant Electric Tools.)

Mounted on buggies, used in stationary drilling stands, or as portable tools, Little Giants tackle and finish scores of drilling, reaming and numerous other jobs with equal facility and dispatch.

What jobs in *your* shops can be done faster, better and cheaper with the aid of Little Giant Electric Tools?

Experienced service engineers at the nearest Company Branch will gladly submit recommendations based upon careful investigation.

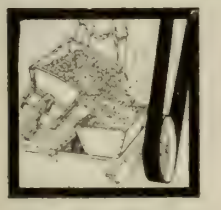
# BELTING

For Transmission

SCANDINAVIA BELTING — TORONTO



For Conveying

GOOD ON BELT SHIFTERS

GOOD IN OILY PLACES

GOOD IN DUSTY PLACES

GOOD IN HOT PLACES

## For Conveying

Use the regular Scandinavia Belt for conveying abrasive materials such as coal, rock, ore, coke, etc., and you will be surprised at the material it can handle per dollar cost.

For non-abrasive material use our special conveyor. This is especially adapted for handling clay, pulp, sawdust, sand, etc.

## And the price is very reasonable.

## For Transmission

The illustrations to the left indicate where this belt can be used to advantage. This belt makes a good general service belt.

*Write Us Your Requirements*

**FEDERAL ENGINEERING CO., LIMITED**

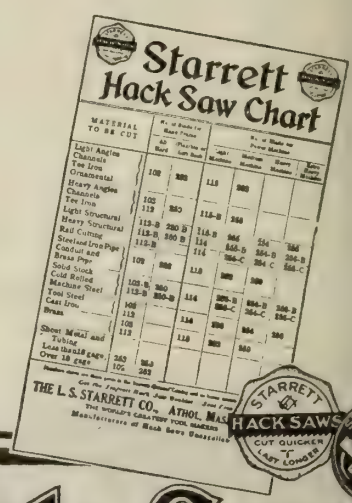
*If interested tear out this page and place with letters to be answered.*



## Ten hours! More than a day's labor! Think of the cost in dollars!

Such was the result of a test between the flexible type of hack saw and an all-hard blade.

Both were designed to cut the same material! Both were carefully run to deliver the utmost service, but the all-hard blade demonstrated from the start that it cut costs by cutting quicker. On power sawing, where weight is needed to make the teeth of a blade "bite" into the stock, the soft-back saw is not practical. Because of its flexibility, pressure makes it "buckle" Without this weight the cost per cut is too high.

For economical power sawing the proper blade for the particular kind of material to be cut is indicated by the Starrett Hacksaw Chart. It will be mailed to you, free. Ask for Catalog No. 22 "3."

# THE JOHNSON FRICTION CLUTCH

## Put Johnson Clutches on Your Countershafts

Here's a countershaft equipped with three Johnson Clutches—two of the single type and one of the double—providing two speeds, a reverse and a light auxiliary drive. An exceptionally neat and compact construction is obtained, light in weight and smooth-running.

Wherever really high-grade equipment is desired, Johnson Clutches are the selection. For general transmission purposes there is no clutch more reliable, and none so adaptable to all conditions. Johnson Clutches in special types have also been incorporated successfully in machinery of all kinds. Their exceptional fitness for this line of work is described in our booklet, "Clutches as Applied to Machine Building."

# Pneumatic Tools in Which "First-Cost" Is Soon Saved in Fewer Repairs

Thor

All Pneumatic Tools are as strong as their weakest part. So in producing THOR tools we have been perhaps over-critical with our factory men on those small, yet important mechanisms which make up the finished tool. But we find the longer wear, the absence of time-losing breakdowns resulting from this extra care, is what has made THOR tools standard equipment in so many factories and shops to-day.

Take, for example, THOR Drills, with Corliss Valves, Pressed Vanadium Steel connecting rods and pistons, roller bearings, each minute detail of construction is ready to stand the severest strain which constant operation may place upon it. The result is THOR tools are many times worth their first cost.

**Send for latest catalogue of THOR Tools for 1921.**

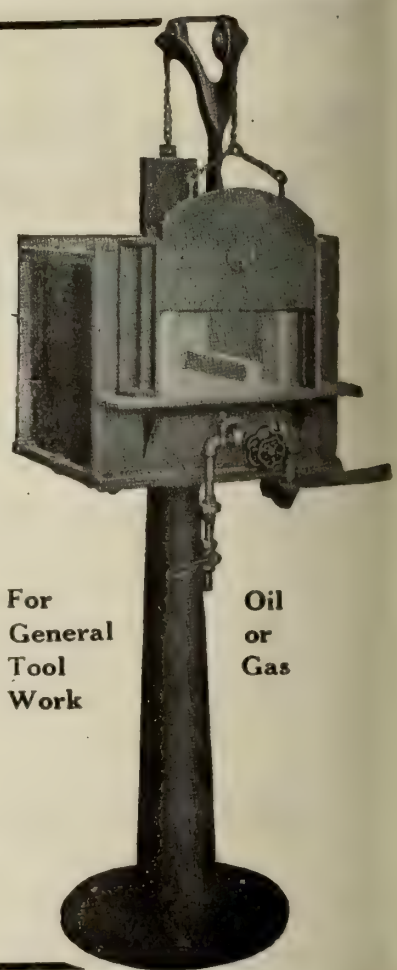
# Heat Under Accurate Control



Here is an important factor in the heat treatment of metals. An intense heat, rapidly developed, and always under accurate control of the operator, are features that distinguish

# BELLEVUE FURNACES

These tool forges are particularly adapted for the requirements of the small machine shop for annealing and tempering dies, cutters, reamers, etc.

Combustion is perfect and no flames come in contact with material. Built to stand the highest temperature. Doors are properly counterbalanced. In every way BELLEVUE FURNACES meet with the demand for durability, efficiency and convenience.

**Let us advise you about your heat-treating problems**

**For General Tool Work**

**Oil or Gas**

## Bellevue Industrial Furnace Company

**Julius C. Hinz, President**

**703 Bellevue Ave. - Detroit, Mich.**

***Representative in Canada: H. W. PETRIE, LIMITED, Toronto, Canada***

Rotary Continuous Heat-Treating Furnaces
Used in Quantity Production of Pressed Steel Parts.

# METALLURGISTS

***The following advantages are secured by the Continuous Method of Heat-Treatment:***

Bringing material up gradually to the final temperature.
Utilizing heat in spent gases to preheat material.
Exposing each piece to heat in same manner, to same temperature, for same length of time.
Uniformity not only of the individual piece but of the sections thereof as compared with the corresponding sections of other pieces.

**DO THESE ADVANTAGES APPEAL TO YOU?**

***Write for Bulletin 217-T and learn whether the continuous method is adaptable to your product and manufacturing conditions.***

# Cleco Pressure-Seated Air Valves

## Bowes Air Hose Couplings—Cleco Never Slip Hose Clamps and Cleco Grooved Hose Nipples and Hose Clamp Tool

**STYLE O.F.** is an Outside Thread Female Pipe End. Made in sizes ⅜-inch to 1½-inch.

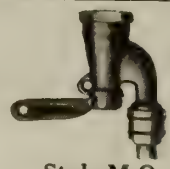
**STYLE I.F.** is an Inside Thread Female Pipe End. Made in sizes ¼-inch to 1½-inch.

**STYLE H.F.** is a Female Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼-inch to 1½-inch.

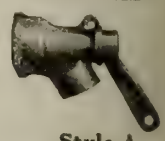
**STYLE H.M.** is a Male Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼-inch to 1½-inch.

**STYLE O.M.** is an Inside Thread Male Pipe End. Made in sizes ¼-inch to 1½-inch.

**STYLE I.M.** is an Inside Thread Male Pipe End. Made in sizes ⅜-inch to 1½-inch.



The Male and Female Ends of Bowes Couplings interchange in sizes ¼-inch to ¾-inch. Sizes 1-inch and 1¼-inch interchange. The 1½-inch ends interchange only with themselves.



### BOWES COUPLINGS

Are instantly connected or disconnected.
They are absolutely air-tight under all pressures.
They quickly pay for themselves by stopping costly leaks.
They interchange in sizes most commonly used.
They have no loose parts to be mislaid or lost.
They are made of brass and will not rust.
The U-shaped Gasket interchanges in couplings ¼-inch to ¾-inch.

### CLECO VALVES

Style P.O.

Style M.O.

Style A.

Style P.O.—Made in sizes ¼ in., ⅜ in., ½ in., ¾ in., 1 in., 1¼ in., 1½ in., 1¾ in., and 2 in. Pipe Outlets. Inlets are one pipe size larger.
Style A—30° Angle Valves, are made in sizes ½ in., and ¾ in.
Style M.O. Valve—Has 1 in. Inlet and Bowes Coupling Outlet. Connects with Bowes sizes ¼ in. to ¾ in.

### CLECO GROOVED HOSE NIPPLES

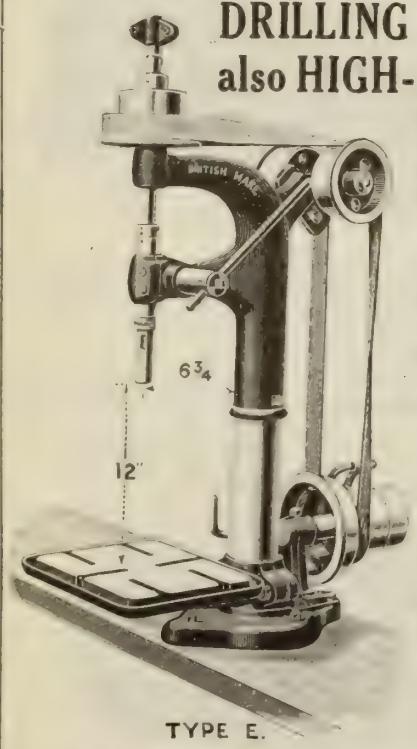
Grooved Nipples when attached to the Hose with Wire Clamps as illustrated cannot "blow out." Wire clamp tool shown below applies the wires to hose.

**The Lightening Hose Clamp Tool** illustrated applies wire clamps at a cost of 1½ cents each.

**In stock:** Riveting and Chipping Hammers, Air Drills, Emery Grinders, Sand Rammers, etc.

**Use Annealed Wire No. 14**

**IMPORTANT:—The Small Leaks in your "AIR LINE" mean serious loss in DOLLARS. Have you any idea of the amount of "Air" wasted in small leaks at your connections? Air Leakage through 1-16 in. opening equals 5.32 cu. ft. per minute at 80 lbs. It will pay you to install Bowes Couplings and Cleco Valves, which will stop costly leaks.**



**Bulletins Nos. 43, 44, 46 and 47 mailed on request.**

**THE MODEL HOSE LINE** illustrated shows correct styles of couplings and valve to use and proper way to attach the Cleco Never Slip Hose Clamps to Bowes Couplings. No "blow-offs" can occur when "Cleco" Clamps are used.

# A Tool That is 50,000 Years Old

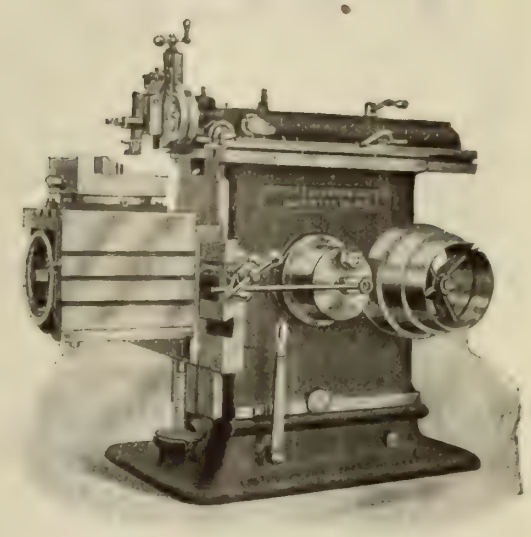
THE invention of the vise dates back probably 50,000 years, and in its most primitive form was made of a forked branch bound with wet root or bark, which contracted as it dried.

From the very earliest times the vise has been one of the fundamental tools of industry—but it is only within a very recent time that industry has realized that every possible improvement in vises was of far reaching importance.

Columbian Sledge-Tested Vises are the most highly improved vises made today. They are the only machinists' vises that are made of malleable iron—and the use of malleable iron instead of cast iron is the greatest single improvement made in vises in hundreds of years.

The removable jaw-faces of Columbian Vises are made of high-grade tool steel and are separately tempered. The corrugations are formed by cutting in two directions on a shaper.

The screw is self-aligning by means of a cone bearing. The depth and width of the beam and its accurately machined bearing surfaces insure absolutely parallel jaws, yet the front jaw works freely all the time.



Columbian Sledge-Tested Vises are sturdy, rugged and durable. Yet they are so carefully made that they are the best vises for fine work. When you order vises specify "Columbian."

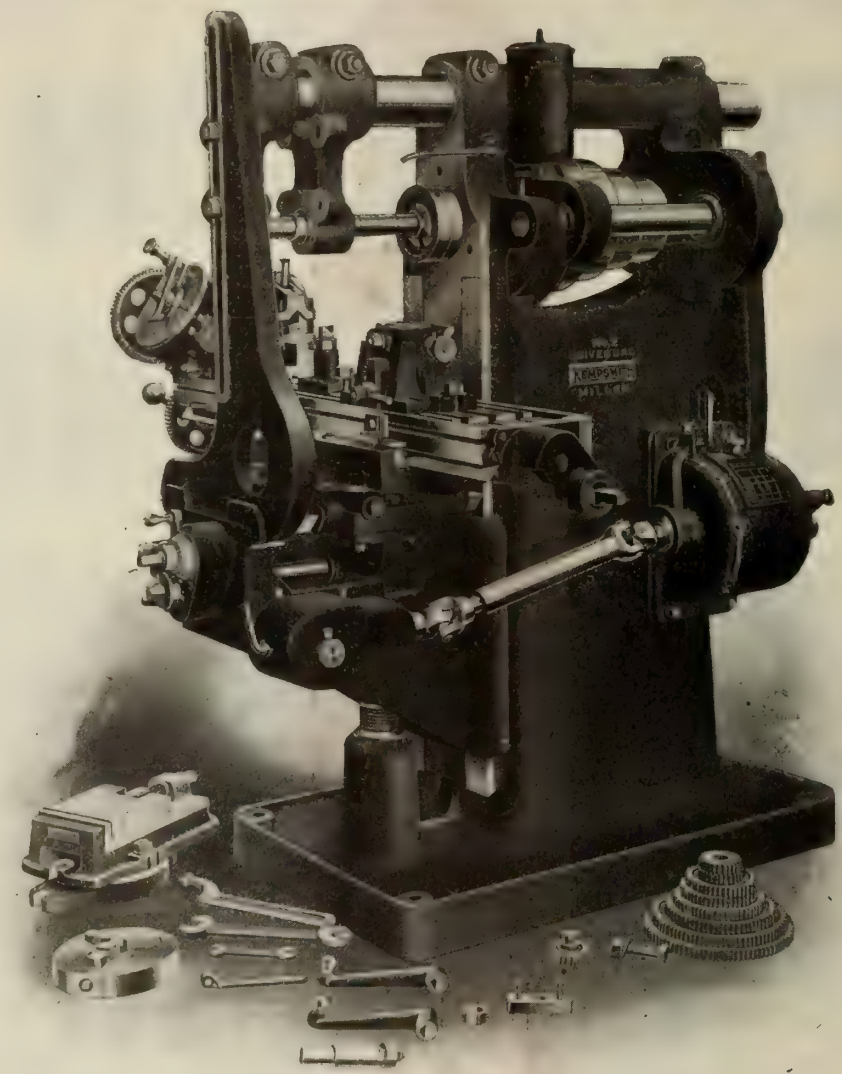
**"Liquid Air" Oxygen Means a Saving in Transportation**



With a network of Factories, not only planned but in actual operation, and a number of Distribution Stations situated at all large centres all over Canada, Purchasers of Oxygen can obtain their supplies at a point very near to the point of consumption. This completely obviates heavy freight charges on cylinders and assures an immediate supply at any time within a few hours and even minutes after the orders are placed.

All cylinders conform to the specifications of the Canadian Railroad Board and are made to ensure safety without unnecessary weight. When purchasing "Liquid Air" Oxygen, you not only save on freight, but in very many cases this expense is almost eliminated.

# KEMPSMITH

## No. 2 UNIVERSAL

Thirty-two years ago the Kempsmith Company began its career in a small one-story frame building. To-day there are four main buildings, aggregating 106,000 square feet of floor area, besides various storage sheds, etc. Every building of the plant is a model of its kind.

It has always been, and will continue to be, a purpose of the Kempsmith Company to produce machines of the highest quality only, suited to the most advanced practice.

Every machine, whatever size or type, is put to test under cuts and conditions purposely more severe than it will encounter in even the most progressive shops and when it leaves our factory it has our positive and definite guarantee back of it.

*Literature will be gladly sent upon request*

## McDougall Crank Shapers

16 and 20 inch.

ARE-MAC-DEE IS A GUARANTEE

### A Bigger Day's Work—

is made possible with McDougall Crank Shapers than with any ordinary Shaper because the McDougall is built on lines especially for this purpose. It embodies the most approved features of the most practical shapers on the market and care has been taken to exclude all non-essential parts.

The column is massive in construction, well braced and reinforced internally. Exceptional strength is also seen in the ram, which is semi-circular in form and of box type. It can be set forward by crank conveniently arranged.

Slides are square, accurately fitted and with broad bearing surfaces.

Have us explain the other salient points of this finely constructed machine. Full details on request.

# For Polishing Wheels, Alundum Grai Brings Increased Production

Polishing wheels set up with Alundum grain have a fast cutting action and give long life—two significant facts for the manufacturer to consider in attaining maximum production at a minimum cost.

Fewer "set-ups" and a greater economy recommend to the manufacturer with modern methods this means of cutting his polishing costs and raising the standard of his production.

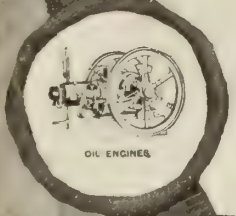
# FAIRBANKS-MORSE

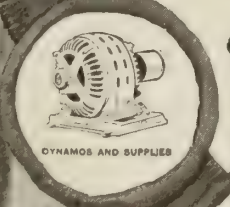


## Speeding-up the Nation's Production

TO meet the nation's insistent call for greater production—production to bridge the gap caused by the long period of hostilities during which our every effort was concentrated on winning the war, the entire Canadian Fairbanks-Morse organization is again bending every effort, exerting its full strength to serve Canada and Canadians.

Here is a Canadian institution backed by a Dominion-wide distributing organization, its branch houses extending across the country, giving a new conception of service to manufacturer, farmer, fisherman—to every branch of industrial activity. Here is an institution which is a dominating factor in Canada, whose name has become the synonym of quality and whose service is recognized in every branch of business where mechanical goods are used.

Our 100% quality mark is the outward symbol of all that this organization stands for. This seal not only marks the standard of quality of Fairbanks-Morse goods, but it represents the ideals of the organization and of the men whose service and advice are yours.



Everything mechanical for factory, mill, farm or motorist
and everything backed by 100% mark of quality.

Ask our nearest branch house for information about anything mechanical.

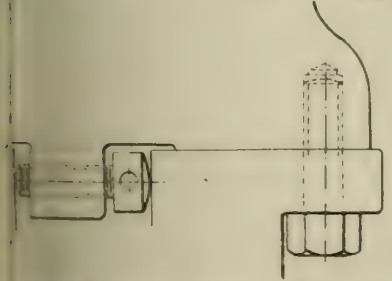
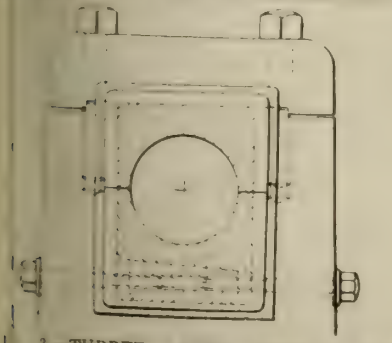
# Correcting the Alignment of Machine Tools

## Various Methods of Correcting the Alignment of Spindles, Slides, Heads, Cylindrical Bearings, Clamping Devices, Turrets, and Other Parts of Machine Tools



By F. HORNER

THERE are numerous forms of adjustment and correction necessary in machine tool construction and operation, comprising such things as the initial setting up, the finer corrections for alignment and squareness, the taking up required before, and sometimes after, trial runs, and the rectification of bearing and slide fits.



In this article we will consider yet another feature, comprising a certain form of correction which is only made at comparatively rare intervals, once at the time of assembling or testing the machine, and subsequently at periods ranging from weeks to months or years, dependent on various considerations. These particular corrections are for putting right the alignments of spindles, slides, head, and various holding devices, and for absorbing backlash which develops through the wear of the parts.

With all the precautions in manufacture, opportunities still creep in for little inaccuracies to arise, partly due to the results of wear, partly to over-strain, and partly to misuse of the machines, or defective corrections in other ways. Cylindrical bearings, for instance, can easily be thrown out of alignment by improper taking up of the wear. So may slides and heads of various sorts, clamping devices, turrets, etc. The most important factor in regard to maintenance of alignment is undoubtedly rigidity, which refers not only to the fixed portions of frames, bases, etc., but to the stiffness of moving parts; if the latter can be sustained with firmness, and are in themselves stiff and rigid, the machine will wear for years in an accurate manner. But if the walls of the framing are weak, easily buckled, and liable to permit of vibration, the chances of retaining perfection of alignment are small.

The effects of heavy loads, including the mass of the slides or tables, the weight of jigs, fixtures, and work, and the pressure due to cutting, are such that the deflections arising from weakness of support tend to wear the parts cornerwise, as it were, instead of in a straight unswerving path. The amount of error produced in a given time may depend upon the line of pressure resulting from the cuts. For example, a good deal of side pressure or localised cutting at one end of a traverse, will more rapidly accentuate errors. Tables will even bend under the influence of weights too severe for their strength, or because a piece of uneven shape is bolted on, and the bolts strain the table up into a slight curve. Here is another cause of alignments getting rapidly out of truth, and this is why so much stress is laid upon the efficient ribbing, bracing, and thickening up of bases, columns, tables, and supports of numerous kinds. In order to secure inertia of a sufficient amount to withstand vibrations, with all their

SCREW FOR ALIGNING LATHE HEAD

3.—TURRET LATHE SPINDLE BOX WITH VERTICAL ADJUSTMENT.

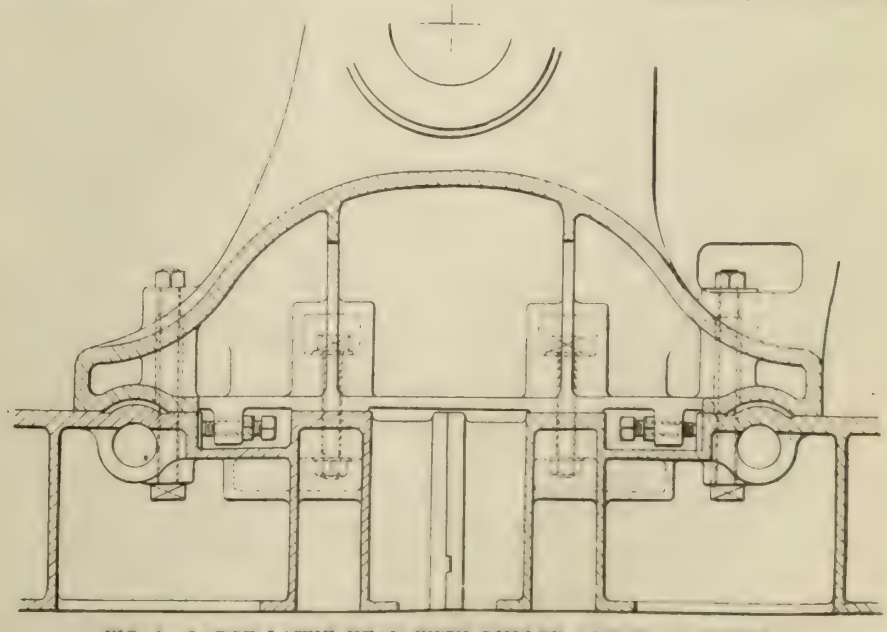


FIG. 2.—LARGE LATHE HEAD WITH DUPLEX ALIGNING SCREWS.

destructive effects upon work and machine, the mass of knees, slides, tables, and spindles must be enough to resist the vibratory influences. The thing, however, must be done properly and consistently, since the strengthening and massing up of one portion will fail to afford proper protection unless the companion elements are also treated properly. Vibration extends to several adjacent parts, and becomes cumulative, hence the necessity for intelligent interrelation of design, and of adequate proportioning also of driving mechanisms, comprising screws, racks, shafts, and of clamping devices.

### Watch the Cutting Pressure

Vibrations, as well as deflected direction of movement, causing unequal wear, are made worse by unbalanced conditions of cutting, and the endeavor should always be made to equalize cutting pressures on opposite sides, along edges, and to provide resisting media in the shape of supports, pilots, steadies and other details. Then the machine will have a better chance of keeping in an accurate condition, while the work will give less trouble in regard to parallelism, even thicknessing, and general alignment and squareness. These important requirements tend to become more and more exacting as pieces have to be tooled to close limits, and guarantees have to be given of the state of accuracy of the machine, or of pieces machined.

Certain occurrences affect the working of machine tools in an irregular and sometimes rather subtle way. The usual line of pressure of a tool may wear bearings and slides in a nearly constant direction, so that the designer is able to anticipate the path of such wear, and provide suitable recompenses. But under some classes of working the wear may turn out to be of an uncertain character, and what is rather awkward, of a local

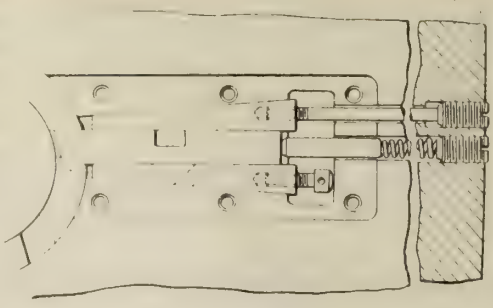

FIG. 3. TAKE UP AND CORRECTIVE STRIPS FOR TURRET LOCKING BOLT.

nature. In the latter event, it may not be feasible to provide anything in the way of an easy corrective method, and the only thing is to properly overhaul the machine at a certain interval of time, and reface or scrape a whole bed or slide so as to restore the pristine accuracy.

Neglect to take up slackness at a sufficiently early period is responsible for some of the faults found in machines while in use. They may proceed with their operations satisfactorily, notwithstanding the slacknesses which have developed to a slight extent, but damage is being done all the time because the contacts are more localized (both in round bearings, and in flat sideways) and wear occurs correspondingly, at sides or on corners instead of over a larger area. And as these restricted areas revolve or rub together they naturally wear faster than if the whole designed bearing surfaces made contact.

### Eliminate Backlash

Many of these remarks apply equally to alignment and to backlash conditions. The presence of backlash in movements has not always such a decisive effect upon the work, but is frequently more of a time-wasting character. But if accurate reversals are desired, backlash need to be strictly eliminated, either by absorbing all of it by adjustments, or by appropriate hand correction before making a fresh movement. It is proposed to consider alignment adjustments first

In the course of manufacturing a machine, the mode of rectifying the alignment as the building proceeds often depends upon certain features in the design. There may or may not be simple way of diverting the alignment of heads, for instance, this depending on how they are attached to the bed Heads resting on vee ways, as a case in point, are automatically aligned, and cannot be re-adjusted by the simple process of swivelling them or pushing them over bodily, which method is easy with heads set on flat surfaces. Sometimes, therefore the latter advantage obtained by discontinuing the vees after the spot where a saddle or slide moves and clamping the head on a flat area Or the vees are still carried along, but special provision is added to the bearing arrangements to permit the spindle to be thrown slightly to bring it in line

In recent years the American or v design of bed has come in for some notice because of the alleged rapid rate of wear that occurs, by comparison with the English, or flat lathe bed. Endeavors have been made to delay the wear the vee bed by chilling the ways, and by modifying the profile in such a manner that an increased width of bearing surface is secured at the place where the principal thrust takes place.

Wear of a bed is both downward and lateral, with the result that work cannot be turned parallel. In the case turret lathes further complication arises because of the several concentric surfaces that require to be turned, bored threaded, etc., and the fact that numerous tools have to be brought into action Any defects in alignment of spindles slides, or in the indexing mechanism are soon released in testing the product. To a certain extent compensations may be made in the operation a few of the tools, which overcome defects present in the machine, but this does not apply to all, nor can it make for all the deficiencies of action. English practice, a favored mode of correcting the alignment of a lathe head through cross-setting screws. The head is tongued loosely into the bed, and either one or two screws set into tongue at each end of the head provide a method of cross setting (and of swivelling) before the holding-down bolts tightened. Subsequent rectifications may be therefore made with ease.

A single-screw lug is illustrated Fig. 1, alternative of two screws be often practised, each screw starting from the opposite sides of the hole, pressing with its head against the tongue. This takes some of the strain off the holding-down screws point not so certain with the one-screw method. On massive lathe heads e

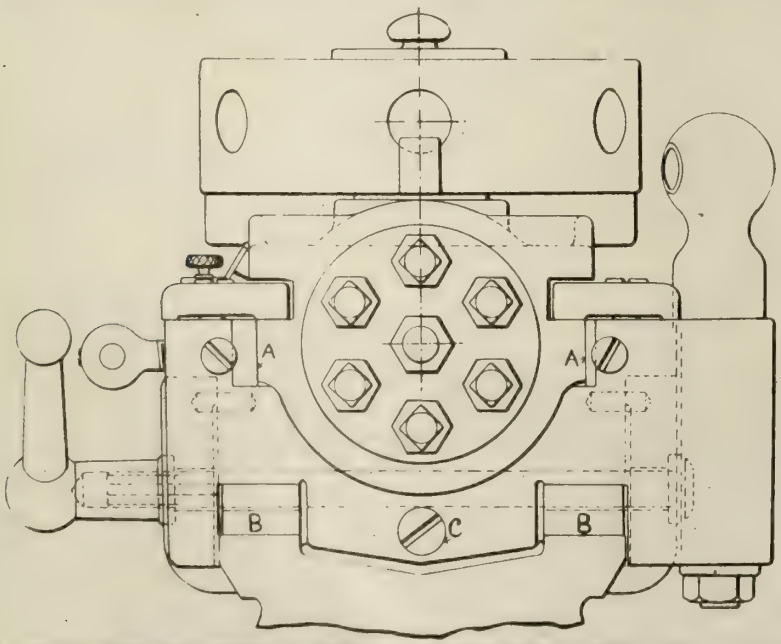

FIG. 4. REAR VIEW OF BROWN & SHARPE TURRET WITH STRIPS FOR LATERAL AND VERTICAL ALIGNING.

...ls are necessarily duplicated, and spead well apart, so as to increase the re...stance to twisting. An example of th... may be seen in Fig. 2.

### Cause for Anxiety

The fit of the loose head is a cause for a...iety on the flat bed lathes because th...re is no automatic aligning feature p...sent, as in the vee top. The tongue o... the poppet must be a trifle slack in the bed to allow of easy sliding, so t...t the groove cannot be depended on f... aligning purposes. The best thing t... do consists in making use of one e...e constantly for every re-alignment, k...ing the tongue fit very freely, so that th...re will be no friction and wear against th... edge. The clamping device is then con...ucted in such a manner that the head is invariably drawn over against this g...ding edge, a guarantee of accuracy, p...vided it is not burred or otherwise d...aged.

A fresh set of circumstances arises w...en heads are cast solidly with their b...s. The opportunity for lateral cor...tion, or for vertical adjustment by s...aping the head is not present. The a...rnative is that of modifying the s...dle position by moving the bearing l...es, or by correcting the path of move...nt of a turret or other tool slide. Both p...ctices are followed by various design...s, preference being given generally to th... latter procedure. If only a vertical a...stment is afforded the spindle, com...sation for the lateral defects of a...nment is arranged in the form of d...ble gibs flanking the turret slide. F... 3 is an instance of height correction f... divided bearings of a head cast in o... with the bed.

Both boxes are machined at an angle u...derneath, to coincide with the wedge s..., and the adjustment of this in e...er direction by means of the pair of s...ws elevates or lowers the spindle n...e. An exceptional practice, of w...ch only one or two examples are ap...ent, is that of fitting the head to a s...bing face on the end of the bed, so th... it can be slid up or down this to b...g the centre height correct.

The lateral alignment of a turret slide, if the headstock possesses no corrective fe...ng, is a matter of furnishing a gib on e...h side and setting these up relatively u...l the turret holes are found to be in alignment with the spindle axis. The g...s are either of the direct lateral closi...g pattern, forced against the edge b... a row of screws, or—which is a better c...struction — they are tapered, and p...ed endwise, giving metal-to-metal c...act all along. An end view of the B...wn & Sharpe turret for the firm's n...w screw machines is shown by Fig. 4; the lateral alignment correcting st...s, of relatively reversed tapers, are le...ered A,A, while vertical adjustments ar... practicable by a one-piece sole or fr...e, tapered from front to back, the p...s which rest on the bed and sustain th... turret saddle being marked B,B.

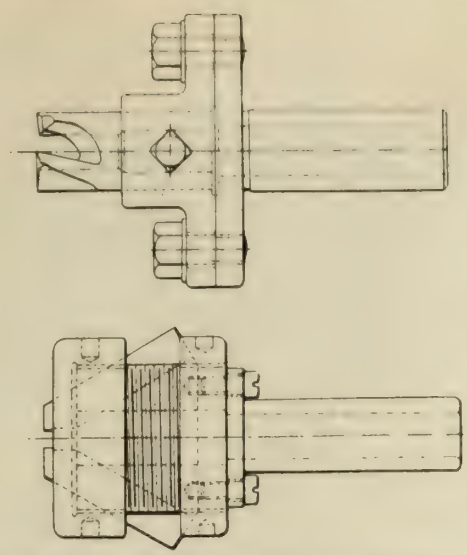

FIG. 6. SET OVER FLANGES FOR HOLLOW MILLS.

There is a screw C located at each end for the function of drawing the frame to or fro.

Given a corrected movement of a turret slide, it does not follow that every tool hole will line up truly. The holes may have been pulled somewhat out of shape, or the indexing bolt may be defective in action. In the latter case the results are uncertain every time the turret is swung around and locked. The correct thing is to have no slackness in the fitting of the bolt, and to be sure that no grit or dirt is present to prevent it from fitting properly into the turret locking ring. Prevention of slackness as regards the bolt can only be ensured by fitting a gib alongside it, so as to press it constantly against the same face all the time, the taper nose of the bolt taking care of the turret position after that. But it should be noted that the application of one gib only has a tendency in time to let the side of the bolt and its contact face wear to one side, hence the double gibbing system, like that in the Bardons & Oliver turrets, Fig. 5, is to be preferred, from the point of view of centralizing.

### Watch the Details With Care

Notwithstanding all the care which may be exercised in putting right such alignments, very small discrepancies are likely to be present, and means are luckily available for introducing a further adjustment in connection with the tools themselves, after they have been placed in the turret. This adjustment assumes the form either of a cross and vertical setting, of such magnitude and direction as may be found necessary, or of a floating hold that constantly accommodates itself to the faint inaccuracies present in the lining up of the turret holes. The first device generally consists of a flanged union with set-screw fastening allowing sufficient freedom before tightening up. This is represented in Fig. 6, showing a holder for a solid hollow mill, and an adjustable ditto. The floating class of holder, employed for such tools as reamers, taps, and dies, has a small degree of looseness in the connection between the parts, so that the tool will adjust itself automatically to the work. This principle, of course, is only applicable to such operations as those of a following nature, on parts already turned or bored, or for such tools as will automatically centre themselves by the effect of the centrifugal force of rotation. Some amount of discretion is required in applying these adjustable and floating holders, otherwise the work may suffer in accuracy or finish from neglect to keep the main alignmehts of the lathe up to a good pitch.

The adjustment of certain other ma-

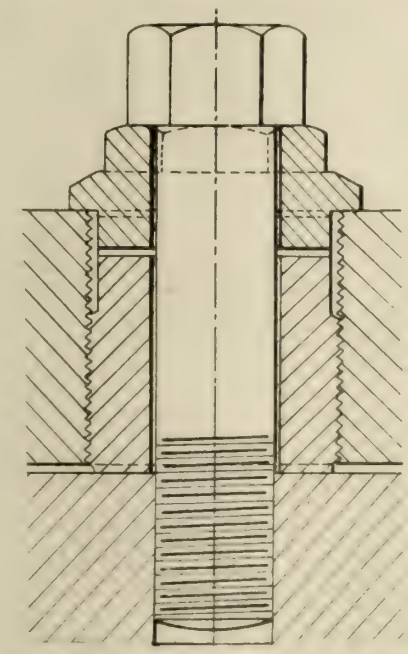

FIG. 7. BUSH AND SCREW FOR CORRECTING AND FASTENING BLANCHARD GRINDER COLUMN.

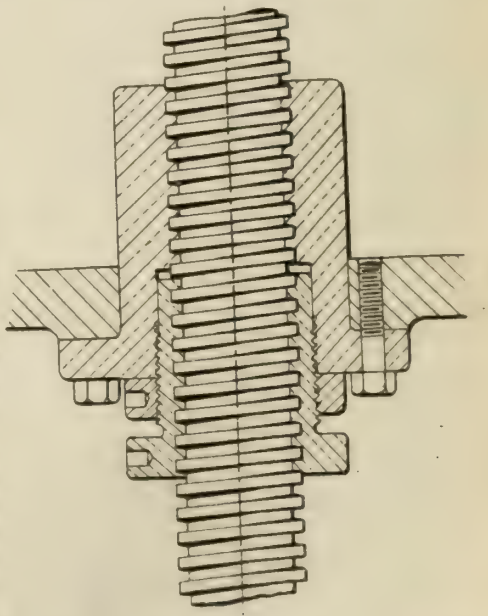

FIG. 8. FEED SCREW PROVIDED WITH TAKE UP FOR WEAR.

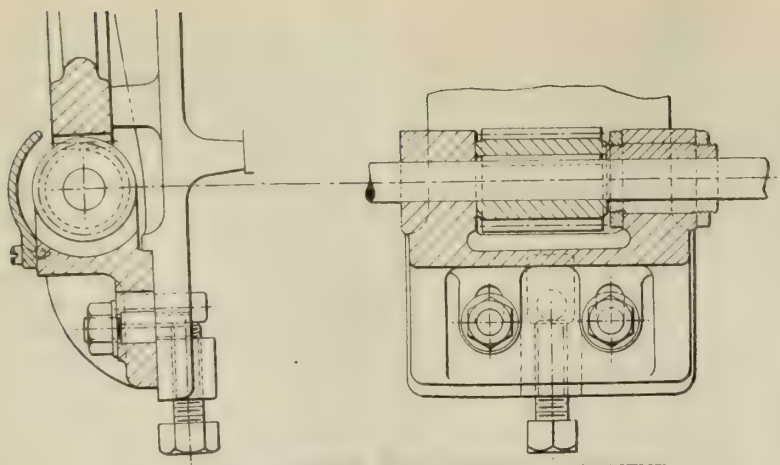

FIG. 9. WORM BRACKET WITH DEPTH ADJUSTMENT.

chine parts is effected in various ways, as may be demanded from the special shape of the machine. If vertical faces are joined, and it is desired to produce a small degree of modification in their mutual relationship, a good method is that of the three-screw principle; a centrally-situated screw or bolt pulls the faces together, and two others flanking it allow for tilting the relative parts. Further locking may be accomplished by other fastenings after making use of these adjusting screws. In such manner a standard or head can be thrown one way or the other to align a spindle or slide, or a table can be levelled in relation to a spindle above it. Some of the lighter type surface grinders require provision for tilting the table to permit concave or convex grinding to be performed; in these examples the tilting arrangement also furnishes a mode of adjusting for level, a distinct construction from that just specified.

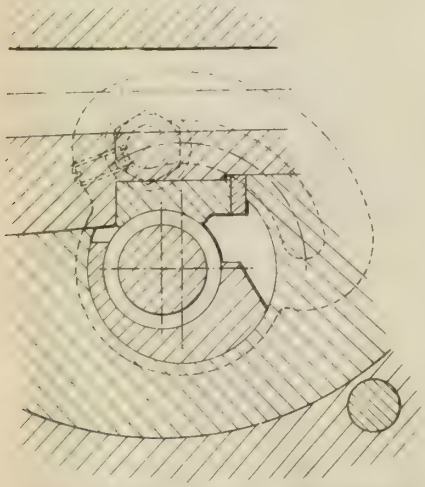
The Blanchard surface grinder is built with a peculiar type of alignment correction, by means of which the massive head carrying the spindle may be tilted in the direction necessary to make the wheel produce flat surfaces. The head does not rest upon the bed, but contact only depends upon three bushings threaded into the base of the column. The state of this three-point support is capable of alteration by suitably manipulating the bushings, so as to raise or lower the head at one or other of the supporting spots. A washer above each bushing connects to it loosely by slot and tongue fitting, so that when the washer is turned by a spanner on its hexagon head the bushing screws its way in or out of the column hole. Then binding is done by tightening the set-screw which passes freely through washer and bushing. The parts are seen in Fig. 7. It may be mentioned that two of the bushings are located at the front end of the head, flanking the spindle head slides, and the other at the rear. The washer on the latter is graduated in order that tilting may be done, and settings duplicated for concave or convex grinding.

In designs of grinding and other machines where rapid change from parallel to tapered working is wanted, a swivel construction is often incorporated by which the slewing of the head or of the wheel spindle base may be accomplished. The return to normal, that is, parallel setting must be accurate, if time is to be saved in trial cuts and measurement, and the change also ought to be rapid. Hence the method of returning to position by reference to graduations does not always commend itself, and a better way is to fix a dead stop, which if kept clean, answers admirably. This must be made with some device for adjustments to make up for wear and other faults which develop. For the very finest class of work even such a provision does not avail any more than setting to graduations, and the only course open is that of trial cuts, a fact which those accustomed to doing long parallel grinding upon machines made with swivel tables will be acquainted with.

### Reversal of Motion

The disadvantages which accrue from the presence of backlash are chiefly concerned with reversals. So long as a pressure is steadily maintained in one direction the effects of looseness in fitting parts usually has no ill result. But such is not the case when a reversal of the motion happens, and undesirable or serious occurrences are liable to arise, together with shock, and destructive action. Two principal situations may be mentioned where backlash is of the greatest disadvantage; one where a screw is used for driving a heavy table, with periodic reversals, the other when a worm pitches round a worm-wheel for indexing purposes. In the first, the looseness of the threads would afford an appreciable interval before the screw commenced to reverse the table, and a sudden and severe shock would come upon the parts and the driving gear, while in the second the accuracy of indexing would be open to question. Some other kinds of backlash are merely annoying, by reason of the interval which elapses before the reversal of a handle or wheel takes any effect, and in regard to others, one needs to be careful to take up the slackness before starting, say a micrometer reading.

A practicable device for the removal or rather absorption of backlash in certain specimens of feeds or drives is that



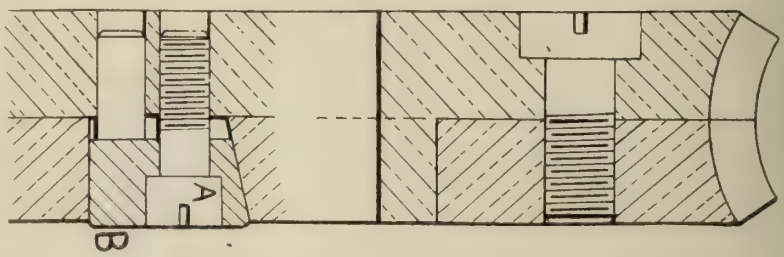


FIG. 10.—THROW OUT AND DEPTH ADJUSTMENT FOR WORM.

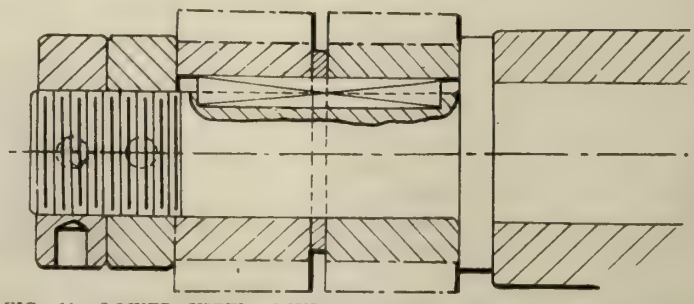

FIG. 11.—LOWER VIEW. DIVIDED WORM FOR TAKE UP.
FIG. 12. TOP VIEW, SHOWING METHOD OF ADJUSTING AND CLAMPING SPLIT WORM WHEEL.

of a counter weight disposed to exercise a continual pull and thus prevent a slide from slacking off. But in the ordinary way the most effectual plan lies in the actual absorption of play between the related elements, as the threads of a screw and its nut, a worm and its wheel teeth, or a block and its link. The take up for threads depends on the diameter, and the type of nut used.

A common fitting is the gland style, (such as in Fig. 8) about half the nut length being bored out, threaded with a fine screw, and fitted with a loose nut. This is turned slightly to consume the slackness and then locked. When a nut is cast in bracket shape, to go alongside a knee or other portion, the dodge of simply splitting the casting and of contracting it with a screw suffices. This does not answer for big nuts, and a suitable form to make these is in halves, one half being bolted fixedly to the under side of the table or other element, and the other half to a short facing, adjusting screws affording the means of forcing this loose section along until the contact with the thread flanks is perfect.

The taking up of backlash in worm teeth can be carried out in either of three ways: (1) Pushing the worm directly in towards the worm-wheel; (2) dividing the worm into halves and drawing them together; (3) making the wheel in halves in a plane parallel to the flanks and twisting one part upon the other.

Construction (1) often requires to be incorporated along with a throw-out motion, for the purpose of spinning the wheel, and it is then necessary to include a dead stop to arrest the inward setting of the worm box after each throw-out has occurred. This stop being finely adjustable gives facility for rendering the degree of backlash nil. Fig. 9 depicts a plain worm box (for a dividing wheel) with the worm adjusted up to the limit; the pressure of the bottom screw against the pin let into the worm box flange forces the latter up, and the two studs and nuts provide for clamping. Dividing heads for milling machines are so constructed that the space available for the worm adjustment device is rather limited. This is the reason for the choice of an eccentric sleeve in many designs, the worm being carried in a casing the outside of which is eccentric in relation to the worm axis. The disposition thus provided allows of withdrawing the worm when its services are not wanted, and of giving a nearly straight line adjustment for backlash absorption. The quadrant, see Fig. 10, on the outside of the head permits of the throw-out, and the stop screw at the one end regulates the entry of worm.

Fig. 11 shows the divided worm, a useful idea if it is not convenient to set into the wheel for take-up, or the worm is employed in conjunction with a long straight segmental nut. The washer between the halves is slightly thinned to enable them to be drawn together a trifle, and correct inter-relation of the worm threads is rendered certain always by the single key fitting the bores. The split wheel may be noted in Fig. 12, showing one of the types of adjustment. Here the halves are united by screws passing through slots and the rotational effect occurs when these are loosened, and the screw A turned in, causing the wedge B to twist the half disc. An alternative adjustment is to screw a peg into one half, bring it up through a slot in the other half, and set by a screw passing through the head of the peg.

## CUTTING A WORM WHEEL OF METRIC PITCH

By G. Barrett

A few months ago I had an accident to a gear cutting machine of German make. The accident caused the breaking of the large worm wheel which revolves the table of the machine.

After carefully measuring the pitch of worm, and the best part of the worm wheel, I decided they were 9 millimetre pitch. This proved to be correct. This wheel was cast and turned in the usual manner, then gashed out in a miller. It was next placed in a horizontal position so as to generate with the special hob which had to be made to get the desired pitch.

In making this hob we had to gear the lathe to cut the metric lead. Here is how we figured it out. There are 25.4 millimetres to one inch, and a metre is 39.37079 inches, which is approximately 39⅜ inches. As there are 1,000 millimetres to the metre, the error is only about 1-200 part less than 39⅜. As the length of the work decreases, so will the error in measurement.

The next step is to bring 39⅜ to an equal number. Since there are 1,000 millimetres to a metre, there are 8,000 in 39⅜ × 8 or 315 inches. The lead screw of the lathe was 2 threads per inch, so we multiplied 315 by 2, making the answer 630 threads in 315 inches, this equalling 8,000 millimetres.

If the screw of one millimetre pitch was required, the ratio between the screw and lead screw of lathe would be 630 : 8,000, or 63 : 800.

As the millimetre pitch is less than that of the lead screw, the small pinion drives the larger gear in the change wheels. In working out the change wheels for any screw of millimetre pitch this fraction is a constant number, and a special wheel had to be cut, having 63 teeth. To find the change wheels required you multiply the constant by the pitch of the screw desired. For example:

Hob to be cut 9 millimetres.

$$\text{Pitch } \frac{63}{800} \times 9.$$

Resolved into fractions we have

$$\frac{63 \times 9}{80 \times 10}$$

By adding a cipher to the 9 and another to the 10 we get the wheels required

$$\text{Driver, } \frac{63 \times 90}{\text{Driven, } 80 \times 100}$$

Very accurate results could be obtained by using a special wheel having 127 teeth with a lead screw of ½ inch pitch.

There are 25.4 millimetres to one inch, and with a lead screw of one inch, pitch and change wheel of 10 and 254, a screw of one millimetre could be cut. This is simplified by a lead screw of ½ inch pitch, and a change wheel of 127 teeth. The result is that a 10 tooth wheel on the change wheel shaft will cut 1 millimetre, and an 11 tooth wheel 1.1 millimetre pitch, a 15 tooth wheel 1.5 millimetres, and so on. For example:

Find change wheels to cut thread 5 millimetres pitch with lead screw of ½ inch pitch.

$$\frac{\text{Drivers}}{\text{Driven}} \quad \frac{5}{127} \times \frac{2}{1} \times \frac{5}{1} = \frac{50}{127} = \frac{25}{127} \times \frac{80}{40}$$

The ratio of these wheels

$$\frac{50}{127} = 39370 \text{ to } 1 \text{ inch,}$$

which would be considered very accurate in relation to our knowledge of the metre and the inch.

## ADVANTAGE OF STEEL FENCES

The day of the wooden fence about the plant is gone. Wooden fences have outlived their usefulness. They never were highly satisfactory, but for want of something better they continued in use until the advent of the present steel-post, wire-netting and barbed-wire fences.

The various systems of steel fencing are more or less designed along the same general lines. They consist of various styles of steel posts, which are set directly in the ground or are imbedded in concrete, and stout steel netting. Fences of this kind protect the plant against trespassers, thieves, firebugs and other undesirables. Indeed, the steel fence is so secure that it virtually extends the storage space of the plant buildings beyond their walls, since the yard becomes just as secure as the store rooms, so far as theft and fire are concerned. It also protects the workmen against accident by preventing their crossing dangerous railroad tracks, taking reckless short cuts, and so on. It simplifies the handling of workmen, since it limits their entry and departure from the works to certain definite gates. All in all, the steel fence marks a big step forward in plant efficiency, both from within and without.

# Adopting Mechanical Ideas in Toy Making

*By J. H. Moore*

"TOY making." The subject does not sound very much like a machine shop article, does it? And yet there is such an amount of machine shop experience embodied in the work accomplished at the school for disabled soldiers at Hamilton, Canada, that the tale is worth the telling.

In this school are manufactured all sorts of toys, but before going into the actual making, perhaps we had better explain the purpose of the school itself. The workers are all returned soldiers who are so disabled that they are unemployable in the open labor market.

When the government came up against the problem of supplying these men with congenial work, they realized that whatever was started must not be run on any hard and fast hours of labor, as the disabled condition of some of the men would prevent their working more than a few hours at a time. This ticklish point was successfully overcome, as will be found out later on in the article.

Having decided on toys as the product the next thing was to start a school where the men could be instructed in the art of toy making. This was done in a humble way in an ordinary dwelling house, but the demand for the toys made became so great that larger quantities were necessary, so the school was moved to the present quarters in the Hamilton Collegiate building. Having thus explained briefly the history of the school, let us see how the men fare in the matter of wages.

### Vocational Wages

The workers all receive their pensions, this amount depending upon their disablement. In addition to the pension, the government supplement this to the vocational standard. The amount is made up irrespective of the worker's productive ability. Suppose a man is so disabled that he can only work a few hours per day. This makes no difference to his wages as it is the condition of the worker, not the amount of work produced that counts.

The regular hours of work are from 9 a.m. to 12 a.m., and from 1.30 p.m. to 5 p.m., but should the medical adviser decide that a man is not capable of working these regular hours, he issues instructions to this effect. These instructions are of course subject to change as the worker improves in health. The medical adviser is at all times the judge of a man's capabilities.

Mr. Harold Saville, the manager of this school, gave us some very interesting facts regarding the method of handling the men.

"You see," he commenced, "the men we have here are really those who cannot get a job elsewhere. Sometimes their body is at fault. Perhaps their mind, or shall we say their perceptive powers are by no means bright. Our task is self-apparent. We must make their work interesting, yet simple. We must so arrange the steps of manufacture that a man cannot very well make a mistake. Some of these men come to us in very bad shape, but it is surprising what interesting work plus easy hours will do for them. The men are never rushed. In fact we would never think of hurrying a man. They can take it easy. A rest room is provided for their comfort, and they have a rest period of 15 minutes both morning and afternoon, so that taken in all it is small wonder that the workers are satisfied."

"I should imagine," I ventured, "that a man would stick around here as long as he could." "You're quite correct," came the answer, "but they don't get a chance except they are still not fit for the open market. You see the men are reboarded every two months, that is, they are brought before a board and examined. This board consists of a doctor, an industrial man, and a vocational officer. After examining the man, this board decides whether he is fit for outside work, or should be re-admitted for a further period to the school. Should a man be pronounced fit for outside labor, every effort is made to place him in a congenial position."

"Do many men improve sufficiently to go out into the open labor market?" I asked. "A great number have been successful in so doing," was the answer. "In fact more than we had reasonably hoped for ourselves. Indeed, if it doesn't sound too much like a boost for ourselves I might say that we have had visitors from all parts of the country looking into our system of training, even to some vocational training officers from Wash-

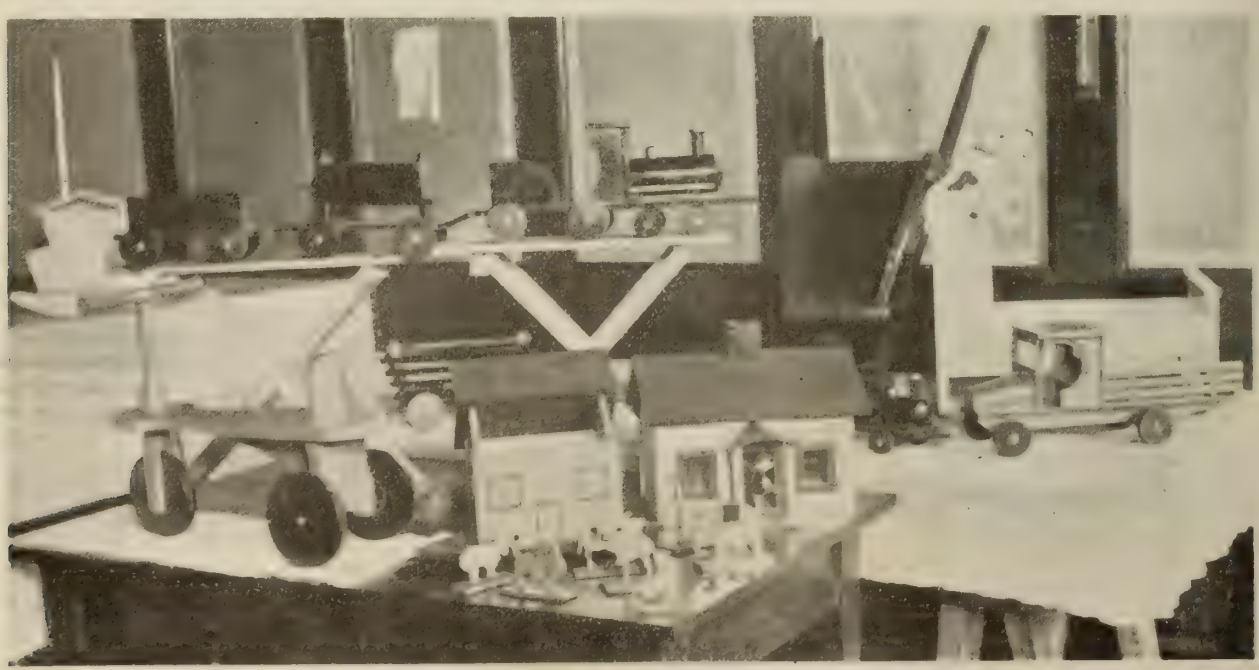

FIG. 1 VIEW OF A CORNER OF THE TOY DISPLAY ROOM.

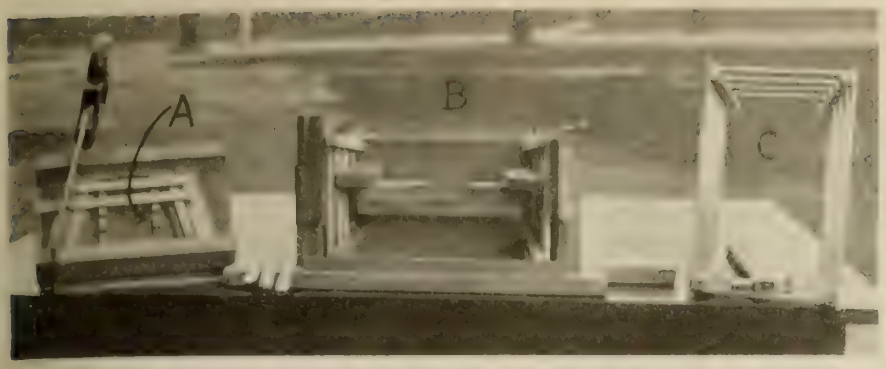

FIG. 2—THE VARIOUS JIGS USED IN THE MAKING OF A HAY RACK BODY

ington, D. C. One thing I would like to emphasize is this. In no case do we work up sympathy. We do not go after business in the way to follow 'buy our toys, as they are made by disabled soldiers.' What we do is this. We place our toys on the open market, employ competent salesmen to sell them, and take our chance. In other words, we make it, as near as possible, a commercial proposition. So far, we have been far from able to supply the demand. Our stock rooms never have a chance to get filled.

"Were you represented at the toy exhibit in the recent Toronto Exhibition?" I asked. "We sure were," was the reply. "In fact we landed second prize for our work. The toys we have made have been sold in all parts of Ontario between London and Niagara Falls, and we hope to still widen this territory."

"What happens to the money you make from the toys?" I asked. "It goes back to the government to help pay for the material and the men's wages." This information having covered in a brief and general way the working of the school itself, let us proceed to the actual making of the toys.

### The Actual Manufacture

The first thought that struck the writer on viewing the school was the system employed. Every toy, no matter what its shape, had a jig of its own. The toy was made in the jig. There was no chance of error, and production was brought up to as good a figure as possible, allowing of course for the condition of the men working on them. A great variety of toys are made, these including hay rakes, kiddie kars, wagons of all sizes, auto trucks, aeroplanes, cats, wheelbarrows, cradles of different designs, ironing boards, engines, dumping carts, dogs, Noah's arks, dolls' houses, etc., etc. A fair idea can be gleaned from Fig. 1 which shows merely a few of the toys produced. The work is not thrown together but made in a good substantial manner, and being made in jigs every toy is alike.

It was realized early in the game that standardization was essential. It was the coming to this decision that caused the making of a jig for every toy. Take for example Fig. 2. Here we see the various jigs used in the making of the body for a hay rack. First let us look at the view to the left of the picture. This is the jig for making the ends of the rack. Note that all the worker need do is place the strips of wood in the slots, one of which is shown at A. After placing these in position he nails them to the braces, saws them even by means of saw shown in bevelled slot, and the end is complete.

After two sides are completed, they are placed in the jig shown at B. Two quick action eccentric clamps hold the ends in place while the side strips are being nailed in proper position. On one side being completed, the work is reversed, and the same procedure gone through. A completed body is shown at C.

### Making an Engine

Next let us consider the making of an engine of similar nature to that shown in Fig. 1. First let us start at the boiler. On referring to Fig. 3, we see a few of the jigs used in the making of such an engine. A shows the first jig used. To make the purpose of this jig clear, we have reversed the piece of wood in the jig. At the bottom of the fixture are two holes, these being of the same size as the holes shown in the boiler (see B and C). On placing the boiler in the jig, the worker turns the jig over, and drills through the two guide holes, which are not shown in the photograph. These holes are drilled with a brace and bit, which has a depth gauge attached.

The next jig, D, is used to fasten the boiler supports. At bottom of this jig are two pins of the same diameter as the two holes already drilled. The boiler sets on these pins, therefore the supports are always in proper location to the holes.

The support being fastened in position, the funnel and dome are placed in position. E shows this stage of manufacture. The axles are next placed in proper position by means of the jig shown at F. Every part must go in a certain place, and must be of correct length, width, etc., to go into position. The axles are fastened to what is known as the bottom of the locomotive.

The coal box and cab are now placed in position, the locating jig G being used. Previous to this another workman has been busy making coal boxes in the jig H. It is unnecessary to go further into the various operations in the making of a toy locomotive. Enough has been given to show the careful thought that has been embodied in its making. All toys are the same. They are made in a strictly mechanical manner. Nothing is left to guess work, and every jig is made as fool proof as possible.

The painting of the tops is accomplished in a separate department set aside for the purpose. When necessary, various colored paints are used. The machine tool equipment consists of a band saw, circular saw, two lathes, a sander, and a jointer.

The toys are not made haphazard. Manufacturing costs are kept just the same as in any other factory. They charge the usual overhead expenses so that this item also figures in the cost of the toys. A system is kept that allows them to tell how many toys they have completed since the start, what balance has been left, and so on.

"What is your limit as far as style of toy is concerned?" I asked. "Give us sufficient quantity to make, and we'll make them, no matter what they are," was the answer received.

One cannot help but admire the work these instructors are doing, and it is perfectly safe to say that the results obtained have more than justified the idea.

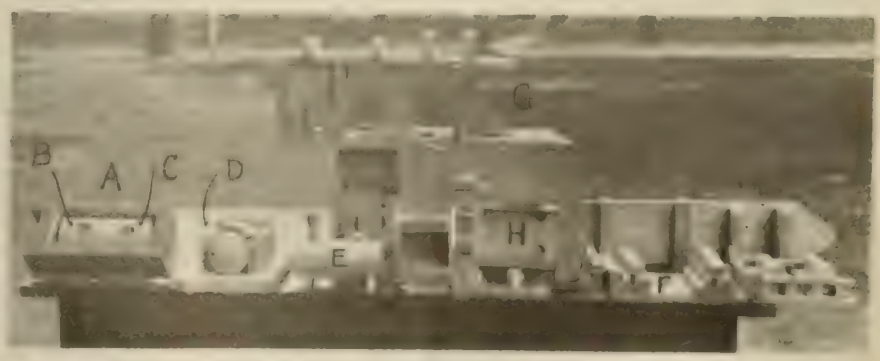

FIG. 3—SOME OF THE JIGS USED IN THE MAKING OF A TOY ENGINE.

# The Machining of Monel Metal Castings

## Cast Monel, Due to Its Extreme Toughness, Requires Tools With Keen Cutting Edges—Methods of Grinding Tools, Hardening and Tempering, Also Lubricants Suggested Are Given

By A. J. HANLON, Technical Department International Nickel Co.

MONEL metal is an individual alloy possessing distinctive machining qualities. Castings, when machined on the lathe, require tools with rounded cutting edges, pronounced back slope, or top rake, and keen cutting angles also a first-class quality of high-speed steel properly hardened and tempered, and comparatively low cutting speeds. Ease of machining is a function of the physical properties of a metal. Experiments made in our own laboratory indicate that cast monel requires more power to machine than mild steel. This power comparison should not be confused with machining methods for these two metals as they are entirely dissimilar.

### Angular Shapes of Tools

Cast monel, due to its extreme toughness, requires tools with keen cutting angles. This necessary keenness may be best obtained without weakness of cutting edges by grinding the lathe tools with certain angular shapes. Tools so shaped permit the use of higher cutting speeds with a minimum of regrindings, both factors of extreme importance in economical shop production practice.

In Figs. 1 to 4 the important angles for roughing and threading tools (both solid tools and tool bits) are specified. The use of a tool holder with ⅜-inch and ⅝-inch bits in itself furnishes sufficient top rake without grinding. The toolholder, for example, holds the bit at a 30-degree angle.

The roughing tool (Fig. 1) is ground with a 13-degree clearance angle and 23-degree top rake. The nose is tapered gradually at an angle of 9 degrees from a plane parallel to the side of the tool and the cutting edge is rounded, with 3-16 inch radius. The sides on the nose are ground with gentle slope from top to bottom to obtain the 9 and 12-degree angles shown. Both angles are measured from a plane parallel to the side of the body of tool. Cast monel metal when turned, gives a long, tough chip. The large rake or back slope ground in the roughing tool helps materially to get rid of this chip by curling it. In that way it is prevented from concentrating the heat generated over the least sectional area (the lip surface), resulting in greater life under working conditions. The clearance angle is made small for the purpose of strengthening the tool, in fact, just large enough to preclude any possibility of rubbing the flank of the tool against the work. When machining a casting with a particularly hard outer skin, the cutting edge may be more blunt with beneficial result. This is secured by grinding the flank of the tool. A tool of this description has less tendency to cut cleanly but is stronger, better withstanding the hard knocks encountered in cutting the skin of any casting, due to sand holes or surface defects.

*The number of uses to which monel metal is being put is constantly increasing. For this reason the present article will be a help to those who have not as yet used this particular metal. The material herein furnishes specifications for lathe tools for turning and threading, also some information regarding lubricants used.*

For either ⅜ or ⅝ inch bits, Figs. 2 and 3, the clearance angle must of necessity be larger than that for bar stock tools, due to the position in which these are held in the tool holder. As no top rake is ground in the tool, this larger clearance angle of 25 degrees does not weaken it. With a ⅝-inch bit, 4-degree side slope should be ground back from the cutting edge in order that the chip may better free itself.

The threading tool, Fig. 4, on account of its pointed cutting edge, has a greater tendency to crumble. For this reason, rake and clearance angles are decreased to 9 degrees and 12 degrees respectively. Side rake, 17 degrees and 18 degrees, is measured from a plane parallel to the side of the body of the tool and is obtained by grinding the side of the nose on a gentle slope from top to bottom. The point of the tool may be ground for any standard thread desired.

The best method of dressing the tool is to turn up the nose or point ⅛ inch above the body of the tool. By so doing the maximum number of regrindings with one dressing may be obtained. The roughing tool shown in Fig. 1 is correctly dressed. The threading tool shown in Fig. 4 has been ground a number of times. With an equal number of grindings the roughing tool would assume a similar shape, in the relation of the nose of the tool to the body. Tools should leave the smithshop with approximately the same angles as the finished tools are to have, to avoid waste on the emery wheel. Forging temperatures for most high-speed steels lie between 1,750 and 1,850 degree F. (yellow heat). During forging operations the temperature should not be allowed to drop to less than 1,600 degrees F. (light cherry or red). In Figs. 1 and 4 the noses are shown dressed straight with the body of the tool. For greater facility, when machining small castings, it is good practice to turn the nose of the tool to the right through an angle of 45 degrees from a plane parallel to the side of the body of the tool.

### Hardening and Tempering

On account of the toughness of cast monel, it is very essential that the high-speed tool steels used in machining should be tempered or toughened after initial hardening. With one particular steel, namely Maximum 000L, excellent results were obtained with the following heat treatment. The temperature was slowly raised to 1,800 degrees F. (yellow heat) and then quickly to 2,300 degrees F. (white heat) and the tool cooled by

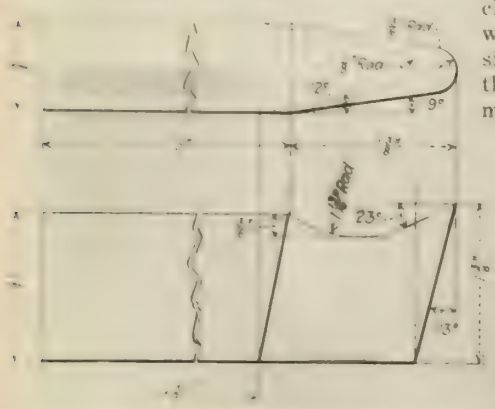

FIG. 1.—DETAIL OF LATHE TURNING TOOL.

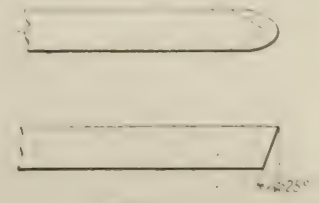

FIG. 2

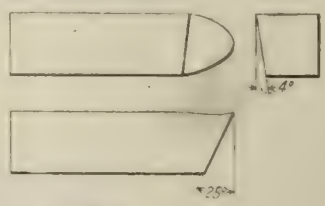

FIG. 3

FIG. 2. A ⅜-IN. ROUGHING TOOLBIT.
FIG. 3. A ⅝-IN. ROUGHING TOOLBIT.

lunging it into fish oil. The temper was then drawn at 1,000 degrees F. (dark red), the tool being allowed to cool slowly in a closed box. Tempering the tool relieves the strains in the metal, giving it a tough rather than a hard cutting surface and materially lessens the number of regrindings necessary for a given amount of work. This hardening procedure follows the general course as laid down for the majority of high-speed steels.

Among the high-speed steels which have given satisfaction in cutting cast monel metal are the Maximum 000L, Peter A. Frassee and Co.; Triple Mushet, B. M. Jones and Co., and Rex AA, Crucible Steel Co. of America.

### Grinding Tools

The tool should first be ground on a dry emery wheel, not being held firmly against the wheel but moved over its surface. The wire edge should be removed on either a common wet grindstone or an oilstone. Care should be taken not to burn the cutting edges. The sides of the flank should be ground first, then the tip or rake angle, and finally the edge should be rounded. On subsequent grindings, approximately the same angles should be retained.

Feeds as shown in the table are recommended. These figures are based on the experiences of a large number of firms. They are for dry cutting. Cooling solution permits the use of higher surface speeds. It will be noticed that a good average speed of 60 inches per minute, ⅛-inch cut and 1-32-inch feed should be used. To secure a better finished surface, a light cut may be taken with small feed and high speed.

The tool should have a true solid bearing on the tool support, which should extend as nearly as possible to a point directly beneath the cutting edge. The body of the tool should be greater in height than in width. The cutting edge should be set slightly higher than the center of the work to obtain the greatest

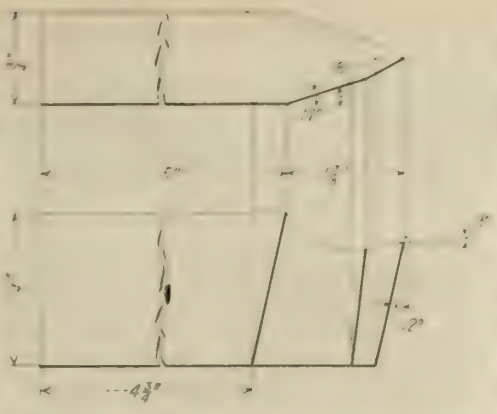

FIG. 4.—DETAIL OF THREADING TOOL SHAPE

shearing effect. No hard-and-fast rule can be laid down, as this height will differ with varying diameters. On small work where a full cut must be taken, with the danger of a dog or chuck interfering with tool carriage before its completion, the roughing tool may be set on an angle up to 30 degrees. For threading all the way to chuck or dog, a threading tool dressed with nose offset should be used.

**Feeds and Speeds for Turning**

| Cut-inches | Feed-inches | Cutting speed Feet per minute |
|---|---|---|
| 1/64 | 1/64 | 150 |
| | 1/32 | 120 |
| 1/32 | 1/64 | 100 |
| | 1/32 | 90 |
| | 1/16 | 75 |
| 1/16 | 1/64 | 85 |
| | 1/32 | 70 |
| | 1/16 | 50 |
| 1/8 | 1/64 | 75 |
| | 1/32 | 60 |
| | 1/16 | 45 |
| | 1/8 | 40 |
| 1/4 | 1/32 | 50 |
| | 1/16 | 40 |
| | 1/8 | 30 |

### Lubricants

For ordinary lathe work, cast monel metal may be cut dry very satisfactorily. The use of a lubricant is sometimes preferable. Among those on the market that have been found to give excellent results are: For cutting, Houghtons' Soluble Oil, 1 gallon to 10 gallons of water, E. F. Houghton & Co.; Equinox No. 1, Lindsay McMillan Co.; Oakite, Oakley Chemical Co. For threading, Cresol No. 1 Soluble Oil, emulsion of 15 parts water to 1 part Cresol No. 1. For cutting and threading, Top Cutting Oil, Frontier Manufacturing Co. For general work, machine oil.

### Examples of Work Done

In Figs. 5 and 6 are illustrated the turning operation on monel metal plugs which have successfully replaced bronze plugs, in connection with Burton's gasoline stills used in the petroleum refining process. The two machining operations necessary, turning to size and threading, are done on an engine lathe. The plug casting is gripped on the square head by a 4-jaw chuck. The tool is turned sidewise at an angle of 30 degrees to prevent interference of chuck and carriage. There is little tendency to dig in, and a wide, tapered chip is removed, thinnest at the finishing point.

A ⅛-inch cut is taken with 1-32-inch feed at 60 surface feet per minute. The point of the tool is set ⅛ inch higher than the center of the work, to obtain the maximum shearing effect. A cut of this size is, in most cases, sufficient to allow the cutting edge of the tool to penetrate under the tough skin of the casting, into the more uniform metal underneath.

The great advantage of the top rake in the lip surface of tools is clearly shown in Figs. 5 and 6. The chip is curled and thrown to one side with the least injury to the cutting edge. Keenness of the cutting edge is thus retained over the longest period of time with resultant good surfacing.

For the threading operation a tool with the nose turned to the right at an angle of 45 degrees is used. The finished thread is completed in three or four passes. The chip curls up very much as does the chip from the roughing tool.

# Renewal of Cylinder Parts on Locomotives

## Various Mechanical Tests Made on Cast Iron Such as Used for the Various Cylinder Parts—Traverse, Tension and Brinell Tests, With Their Results

By C. H. STRAND

THE RENEWAL of cylinder parts on locomotives has always been a sore spot in the side of railroad executives. The maintenance cost has been a considerable item. For this reason, if for no other, this portion of Technologic Paper No. 172 of the Bureau of Standards, Washington, D. C., should be interesting.

At the request of the former U. S. railroad administration, the bureau of standards has investigated the mechanical, chemical and microscopical properties of a number of packing rings furnished with service-mileage records, as well as arbitration-test bars, chill-test specimens, and miscellaneous samples from different manufacturers. All of this material was cast iron such as used for the various cylinder parts. It was desired at the same time to review the previous work and specifications on this subject, to ascertain as far as possible the practices of the different foundries and to suggest such revision of existing specifications as would be warranted by the results of the present and of earlier investigations.

The samples, 131 in number, were furnished to the Bureau of Standards by the U. S. Railroad Administration. The first samples were received April 2, 1919, and the last September 26, 1919, nine foundries supplying specimens.

### Mechanical Tests

The mechanical tests made at the Bureau of Standards consisted of transverse, tension, hardness, and fracture tests of chill-test specimens.

Transverse Tests.—Thirty-four arbitration bars, ordered made in accordance with the standards of the American Society for Testing Materials, from six different manufacturers, were tested.

When the packing rings furnished were sufficiently large in size, specimens for small transverse tests were machined from them also. It is not to be expected that these results will be similar to those on unmachined arbitration bars, because of the absence of skin or surface hardness.

Tension Tests.—After breaking the arbitration bars in the transverse tests, the broken pieces were used to determine the tensile strength of the material. Tension tests were made from packing rings furnished by four foundries. From the tension tests, at least, there appears to be some more or less definite relation between laboratory and service tests.

Brinell Hardness Tests.—Brinell hardness tests, using a 10-mm. ball with a pressure of 3,000 kg., sustained for 30 seconds, were made on flat, longitudinal sections of the arbitration bars. Approximately ¼ in. of material was removed by the shaper to obtain a surface for the Brinell tests. As there is a variation of only 10 points from the maximum to minimum hardness, it is concluded that, in view of the widely varying quality of the irons as indicated by other tests, the Brinell test does not satisfactorily measure the quality of iron for cylinder parts.

The Brinell hardness tests of packing rings and bushings indicate that the castings themselves are considerably softer than the arbitration bars. This is undoubtedly due to the fact that the slower rate of cooling of the former results in a higher graphitic carbon content.

Chill Tests.—Chill-test specimens were received from four foundries and broken at the Bureau of Standards, four to six samples of the product of each foundry having been submitted.

### Chemical Analysis

Chemical analyses were made of one of each of the arbitration bars from each of six foundries. The various bars were quite uniform in total, graphitic, and combined carbon content. The silicon and sulphur contents, however, varied within rather wide limits, the former from 1 per cent. to 1.47 per cent. and the latter from 0.051 per cent. to 0.167 per cent. The phosphorus content varied from 0.37 to 0.56 per cent.; manganese from 0.36 to 0.90 per cent. It is generally recognized that there should be at least three times the percentage of manganese as sulphur present; otherwise, sulphur will combine with iron instead of manganese, and brittle material will result.

In general, the silicon, and naturally the graphitic carbon is higher in the packing rings, bushings, and similar castings than in the arbitration bars. A ring which gave 93,000 miles in service showed no unusual characteristics in chemical composition.

### Metallographic Examination

The samples were polished and examined microscopically both before and after etching. Heat tinting was found to be very suitable for revealing the irregularly shaped masses of phosphide eutectic and at the same time allowing the black flakes of graphite to stand out clearly. Micrographs were taken only of typical samples selected for purposes of illustration.

Some attempt was made to correlate the microstructure with the endurance in service, but, due to the many variable factors, it was realized that any very close comparisons were apt to be misleading. The inhomogeneity of cast iron made it somewhat doubtful that the small sample used for metallographic examination was representative of the whole. In some instances, however, with the aid of the principles governing the constitution of gray cast iron, the samples could be approximately classified, and the service records bore out fairly well the predictions that could be made of mechanical qualities from a study of the microstructure.

The microscope is most useful in determining the size, amount and distribution of graphite flakes, amount of combined carbon, and to some extent the physical soundness of the castings.

Conclusions are drawn and recommendations made as follows:

On the basis of test made by inspectors of the U. S. Railroad Administration and of the Bureau, which were substantially in agreement, it is concluded that air furnace or so-called "gun iron" is more uniform in character and on the average of somewhat better mechanical properties than cupola iron. The latter, however, often equals or even excels in mechanical properties the specimens of air furnace iron tested in this investigation. The sulphur content of the air furnace iron examined seldom exceeded 0.06 per cent., while the cupola iron varied in sulphur content from 0.10 to 0.17 per cent.

It was impossible, except in a very general way, to find any correlation between the quality of the iron as developed by laboratory tests and the mileage obtained in service. This is explained by the fact that many other factors besides the quality of the iron enter into consideration in the service results, namely, design, lubrication, method of handling the locomotive, topography of the country, character of water used in the locomotive, etc. It is for the reasons cited above that the conclusions and recommendations of this paper are based essentially upon the results of laboratory tests.

The present specifications of the American Railway Master Mechanics' Association are somewhat lax in the requirements for mechanical properties. It

is recommended that the transverse-strength requirements of a 1¼-in. arbitration bar on supports 12 in. apart be increased from 3,200 to 3,500 lb. for castings ½ in. or less in thickness, and from 3,500 to 3,800 pounds for castings over ½ in. in thickness. It is further recommended that the minimum deflection requirements for both cases be increased from 0.09 to 0.11 in. The rate of application of the load shall be from 20 to 40 seconds for a deflection of 0.01 in. The division line of the casting thickness is changed from ⅝ in. of the American Railway Master Mechanics' Association, to ½ in. in order to conform to the recognized standards of the American Society for Testing Materials. Two arbitration-test bars, cast as specified, should be poured from each ladle used for one or more castings.

**Composition Recommendations**

It is preferable to leave the chemical composition and the melting process used to the manufacturer, depending for the most part on the mechanical tests, and of these primarily upon the transverse test. The existing specifications allow a maximum of 0.70 per cent. phosphorus and 0.12 per cent. sulphur; there are no developments in this investigation which would warrant a revision of the maximum permissible amounts of these elements.

For the chill test a sample of the iron shall be taken before pouring and chilled in a cast-iron mold. The sample shall be allowed to cool in the mold until it is dark red or almost black, when it may be knocked out and quenched in water. On being broken, it must show a close-grained gray iron, with a well-defined border of white iron at the bottom of the fracture. The depth of the white iron must not be less than 1-16 in. as measured at the center line, for castings ½ in. or less in thickness, nor less than ⅛ in. for castings over ½ in. in thickness. One chill test shall be poured from each ladle of metal used for one or more castings. The specimens may be cast in adjacent molds, but in such cases a space must be provided between the molds.

Castings shall, of course, be smooth, well cleaned, free from shrinkage cracks and from other defects sufficiently extensive to impair their value, and must finish to blueprint size.

The purchaser, or his inspector, shall be given a reasonable opportunity to witness the pouring of the castings and test specimens, as well as to be present when the mechanical tests are made. Inspection shall be made at the place of manufacture, and the manufacturer shall also furnish the facilities for making the mechanical tests, if desired.

## SUBSTITUTES FOR BRONZES

The shortage of many metals in Germany during the war period forced German manufacturers to adopt various substitutes. These are discussed in an article in a recent issue of "Stahl und Eisen," and translated in the "Journal of the American Society of Mechanical Engineers."

Crankshaft housings for submarine engines have to be built of a special bronze having very high mechanical qualities, such as high tensile strength and high percentage of elongation. Since the beginning of 1915, due to the shortage of metals, these crankshaft housings were made of cast steel, which did not lead to any particular difficulties, and, indeed, with the construction of larger sizes of submarine engines, proved to be an advantage, as it gave to the housing a greater rigidity. On the other hand, the machinability of the material was not so good as that of bronze.

All the screws, bushings, etc., which before the war were made of bronze or copper castings, had to be of iron and tin-coated in order to protect them against rust. This was done by the Schoop process. On the other hand, parts which used to be made of aluminum castings were during the war made of thin sheet iron and then galvanized.

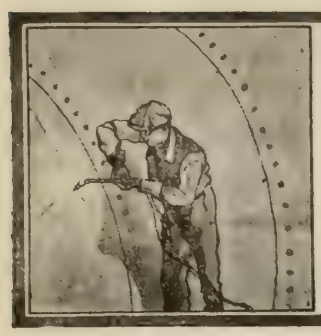
Considerable trouble was experienced with piping. The former copper piping was replaced by steel piping, galvanized inside and out. The zinc coating did not prove satisfactory, however, as it was rapidly eaten away by sea-water and salty sea air. The pipes then were protected by lead, which, however, did not adhere well to the steel, and chipped off easily under mechanical influences. It therefore proved necessary to protect the piping by two coats of metal—zinc first and lead afterwards. This required great skill in manufacture, and a close control of the temperatures at which the metals were applied, and was therefore not wholly successful.

Vigorous efforts were made to conserve tin. Bronze bushings or parts under heavy stress (such as steering gears) used to be made of a bronze with a 15.5% tin content. During the war these bronze bushings were made of an alloy containing about one-third less tin and were not cast in sand, but in a metal mold so as to give them a greater hardness. This was based on investigations made in 1910 by Heyn and Bauer, which indicated that the hardness of a copper-tin alloy is really a matter that may be controlled either by variation in tin content, or by the proper control of temperature conditions during cooling, and, in particular, by the velocity of cooling. It should clearly be borne in mind that this hardening by rapid cooling is possible only with bronze, and not with brasses.

Bronze bushings with a tin content of 10% were machined, and after having been set in their seats were hardened on their surfaces by having a mandrel driven in under high hydraulic pressure. Parts not subject to heavy stresses were made of zinc castings, and it appears that the strength of such parts was materially affected by the heat treatment to which they were subjected.

An effort was made to produce a bearing metal containing 42% tin, 42% lead, 2% copper, and 14% antimony, but it has not as yet been carried to a successful conclusion.

Considerable trouble was experienced in attempts to find suitable metals for use in nozzles through which water, steam, gases, or acids are discharged under pressure. Here, in addition to other conditions, the tendency to corrosion and erosion had to be met. In particular, in injectors attempts were made to substitute cast-iron nozzles for bronze, but it was found that the former did not stand up well when used with either steam or hot water. The inner wall of the nozzle was strongly corroded, which interfered with the efficiency of the apparatus.



## GRADUATES TAKE NOTICE

A rather interesting booklet entitled "A Few Brown & Sharpe Graduates" has just been issued by the Brown & Sharpe Manufacturing Company, Providence, R.I. The contents are especially interesting because an attempt has been made to compile a list of names of men who have served an apprenticeship at the Brown & Sharpe plant, these men having become graduates. This concern hope to make their list still more complete, and request that any man throughout the country, who served his apprenticeship with them, send in his name and address direct to their office at Providence.

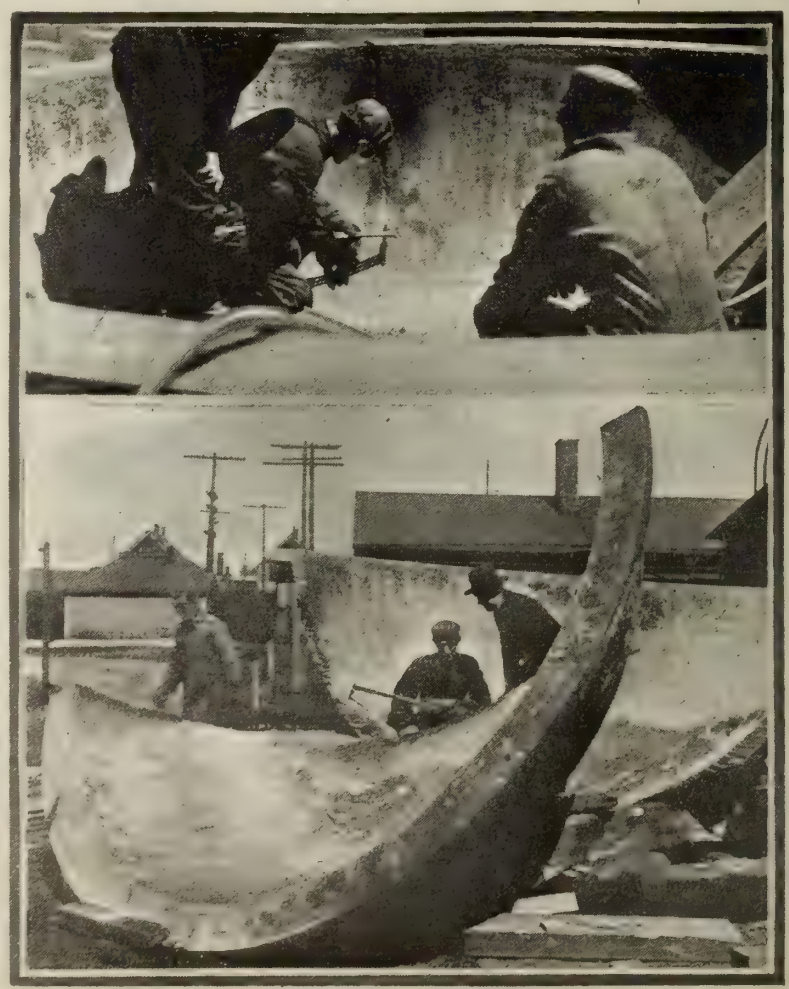
This concern takes a very justifiable pride in its apprentice system, and states that out of an organization of over 7,000 people, the executives, with few exceptions, were formerly apprentices.

## DRILLING HOLES IN GLASS

You can drill small holes in glass with a diamond point resembling that used for china riveting, or with a dead hard steel drill, says Practical Engineer. Use a lubricant of turpentine or oil of spike. Large holes can be rapidly made with a piece of copper tube having a serrated edge fitted with crystals of carborundum. It is not the hardness of the glass that causes the trouble, but the heat created by the friction of the drill. It will be found preferable to leave the glass in cold water where the experiment can be carried on, the water preventing undue heating with the consequent fracture of the glass.

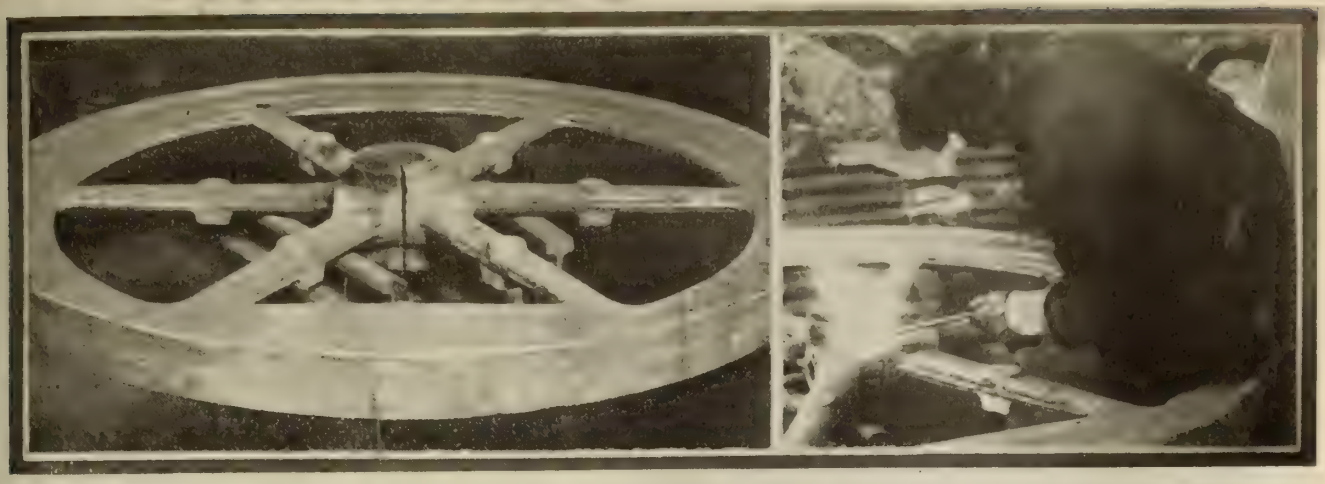
# WELDING AND CUTTING

## Cast Iron Cutting With the Oxweld Blowpipe



### Instructions For Cutting Cast Iron—How to Cut Poor Grades of Cast Iron, Also Good Grades—General Instructional Data for the Operator

INSOFAR as their experience has been given to the public, the findings of the investigators in the field of cast iron cutting agree in indicating that, where pressure blowpipes are employed, some supplementary or specially designed mechanical part is essential. In one instance it is an attachment for preheating the oxygen; in another, a specially constructed tip. According to the Oxweld Acetylene Company, Newark, N. J., and Chicago, their experience seems to have demonstrated to them that general service cutting blowpipes of the injector type require no special attachments, no alteration of the stock torch being necessary because of the solid stream cutting jet and the long preheating jets, which converge toward and are drawn down into the cutting by the cutting jet, thus intensifying the temperature to a point where a special device for preheating the oxygen or a special tip is not necessary to propagate the cut.



According to them the reason blowpipes have not accomplished this work, excepting where specially designed for it, is that it has been impossible to adjust general service blowpipes of that type to give strong flames carrying the necessary excess of acetylene. With some pressure blowpipes fairly good flames have been obtained, and with them it might be possible for a very skilled operator to gradually obtain a cut through the metal, but undoubtedly the operator would take a long time and a real cut would not be obtained.

The Oxweld blowpipe was not originally designed with a view to cutting cast iron, but, after exhausive experiments, a method of operating the torch in cast iron cutting was developed, and it can be mastered by the average operator almost as easily as the method employed for the cutting of steel. There is, however, a decided difference in respect to procedure. In practice, cast iron cutting with the Oxweld blowpipe differs from steel cutting in that: It is necessary to use heating flames having an excess of acetylene; second, it is necessary to hold the blowpipe nozzle farther away from the metal, and third, it is necessary to preheat for a longer period for cast iron than for steel, since the cast iron must be almost molten before the cutting reaction will start. Steel ignites at a temperature well below its melting point. Lastly, it is necessary to continually oscillate the nozzle to maintain the cut. A cast iron cut, if properly handled, and if the material is of good quality, will have an appearance about equal to that of a fair cut in steel.

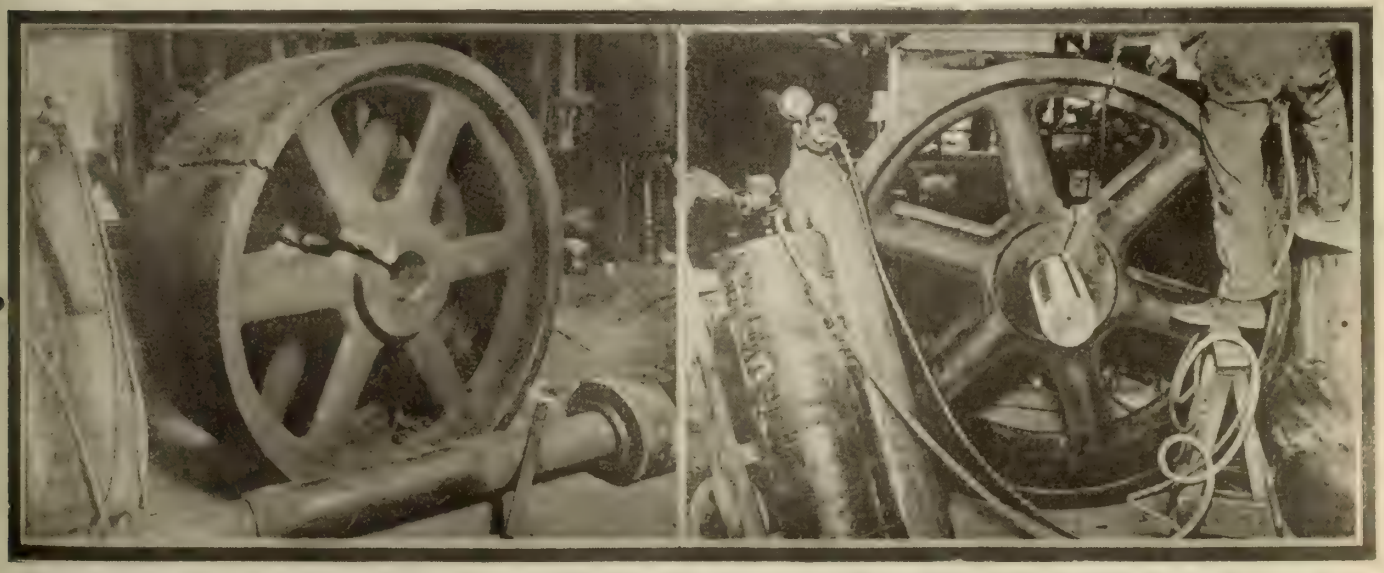
The time required for cutting a given section of cast iron is about twice that

THIS SIXTEEN-TON CAST IRON MELTING POT WAS CUT IN TWO HOURS, THIRTY-FIVE MINUTES. THE POT WAS 12 FT. DIAMETER, AND HAD A FLANGE 1 FOOT. WIDE AT THE TOP. THE CUT MADE WAS SEVENTEEN FEET LONG.

TWO VIEWS OF WHAT CAN BE ACCOMPLISHED WITH THE TORCH ON FLYWHEELS.

required for cutting a similar section of steel. This makes the cost considerably higher in the instance of cast iron, and tends to restrict its application in many places where one might suppose it would be generally useful. For example, the inexpensive methods employed for removing risers from castings in iron foundries preclude the use of oxy-acetylene as an economical means of performing this class of work. Further, the cutting off of risers from chilled iron castings is usually not practical because the surfaces cut are likely to crack or check, due to local heating.

The use of cast iron cutting is, however, being appreciated in the steel mills, where it was introduced more than a year ago. In those plants its demonstration was received enthusiastically, and cast iron cutting has since been used daily in that and other industries for removing broken machinery parts such as pinions, gears, fly-wheels, housings, etc. The removal of such parts by old methods usually required several days because of frozen shafts, bolts, etc. With the cutting blowpipe the broken part, and sometimes parts adjacent to it, are cut quickly, the parts removed, repaired, or new parts installed, all within a few hours.



### Instructions for Cutting Cast Iron

The blowpipe manipulations for cutting good grades of cast iron and for cutting poor grades of cast iron are quite different, and are both described below. Although there is a difference in the manipulation of the blowpipe, the oxygen pressures used and the adjustment of the flame are the same for both grades of metal.

In cutting good grades of cast iron first adjust the oxygen cutting regulator to give the correct pressure as shown in the cast iron cutting chart for the work to be done, having the blowpipe cutting valve open. Then close cutting valve. Next open oxygen valve one-half turn, and acetylene valve fully, and light blowpipe. Open cutting valve and adjust acetylene valve to give flames having an excess of acetylene and of the length shown in the cutting chart. Then close cutting valve.

The third step is to hold the blowpipe so that the nozzle points backward at an angle of 45 deg., with the inner cones (not the excess cones) ⅛ inch to ¼ inch above the surface. Give the nozzle a swinging motion describing semi-circles over the end of the line of cutting and heat a semi-circular area about ½ inch to ¾ inch diameter to a bright cherry.

Next move nozzle just off the heated edge, open cutting valve quickly and move nozzle (at 45 deg.) forward along the line of the cut with the same swinging motion. While advancing the nozzle, gradually straighten it up so that it is about 75 deg. pointing backward when at the inner edge of the previously heated semi-circular area. After this advance nozzle about ¼ inch to burn off the molten surface, then quickly move it backward to burn through the comparatively dark layer and lower section, then hold it steady for a moment to heat the upper surface. This movement can be best practised by counting as follows: 1 forward, 2 back, 3 hold; 1 forward, 2 back, 3 hold, etc.,

THESE TWO VIEWS SHOW HOW A LARGE PULLEY WAS CUT IN ORDER TO REMOVE AND PRESERVE A FROZEN SHAFT. NOTE THAT THE SHAFT IS IN PERFECT CONDITION.

GENERAL VIEW OF THE POT SHOWN IN OTHER VIEWS.

etc. Continue moving nozzle in this manner at the rate of about one complete cycle per second. When the far edge is reached, carry nozzle over the edge and across the other surface, holding it at about the angle of the lag, and cut through the lag section.

### Method for Cutting Poor Grades of Cast Iron

Follow the directions given for cutting good grey iron, except that instead of using the peculiar motion explained, advance the nozzle slowly, describing semi-circles from about ¼ inch to ½ inch wide across the line of the cut, holding the blow pipe at about 75 deg. pointing backward.

In cutting cast iron, a dark layer will be found extending down from the top surface about 1 inch to 1½ inch. Below that layer the material will be bright, having an appearance about the same as steel. Be sure that the forward and backward or the semi-circular movement of the nozzle allows the blowpipe to cut almost perpendicularly through the dark layer. The lag must not start until below that section. Particular attention must be paid to this condition.

If cut is lost, move nozzle back along one edge of the kerf about ½ inch and describe semi-circles lapping that edge and that point where the cut stopped. It the cut is not readily resumed, carry the semi-circles over to include both edges of the cut and the point where the cut stopped. Always wear heavy asbestos gloves and suitable clothing to the body, face and head, because cast iron cutting is a very much hotter operation than steel cutting. Always make sure of ample protection from the heat before starting so that it will not be necessary to stop the cutting operation to take shelter or provide further protection.

There has been no more interesting recent development in the oxy-acetylene field of research than the successful application of oxygen to the cutting of cast iron. Curiously enough this old enigma of the industry appears to have been solved contemporaneously, if not concurrently, by separate investigators and in entirely different ways. Following publication of instructional data in March of the present year, the Oxweld Acetylene Company staged a demonstration of cast iron cutting for the edification of its employees. This demonstration was held in April and was intended to be a strictly private affair; but, through a betrayal of confidence on the part of a photographer, prints of pictures taken at the time were sold to the newspapers and appeared in rotogravure in the Sunday issues. A month or more after this there appeared the first of several articles on this subject. At the present stage of development cast iron cutting may be accepted as an established fact, but not as a concluded study, and the future may be looked to with every confidence that it will yield much of interest and value in the general direction of increased economy and practical utility of the process.

### CAST IRON CUTTING CHART

| Size of Nozzle | Thickness of Metal. In. | Oxygen Pressure Lbs. sq. in. | Length of Excess Acetylene In. |
|---|---|---|---|
| | ½ | 45 | |
| | ¾ | 50 | |
| | 1 | 55 | |
| No. 3 | 1¼ | 60 | 1 to 1½ |
| | 1½ | 65 | |
| | 1¾ | 70 | |
| | 2 | 75 | |
| | 3 | 85 | |
| | 4 | 95 | |
| | 5 | 105 | |
| No. 4 | 6 | 115 | 1 to 2 |
| | 8 | 125 | |
| | 10 | 155 | |
| | 12 | 175 | |

This chart shows about the same gas values recently published by other investigators in the cast iron cutting field.

### FUELS ON RAILWAYS

Important trials with pulverized coal and "colloidal fuels" have been carried on the Great Cental Railway, England. Colloidal fuel is powdered fuel suspended in thick oil, and pulverized coal is dry coal reduced to a fine dust. The trials, which were made in comparison with ordinary coal, showed that the special fuels could easily maintain a full head of steam with a high degree of superheat, even on heavy gradients and sharp curves. Locomotives adapted for burning pulverized coal or colloidal fuel show an economical freedom from ash-pan cleaning, smoke-box cleaning and repairs, fire cleaning, and so on. Further, when the locomotive is delayed in a siding there is much less waste of fuel than in the case of ordinary engines.

### ELECTRO-PERCUSSIVE WELDING

In a paper recently presented at a meeting of the Pittsburgh section of the American Welding Society, Mr. D. F. Miner, the author, discusses recent development in electro-percussive welding. This form of welding is a process which is primarily intended for manufacturing applications, where large quantities of duplicate parts are to be produced. The apparatus in its earlier form utilized the electric discharge from an electrolytic condenser consisting of aluminum plates immersed in an electrolyte of borax solution. A scheme has now been evolved for utilizing electrical energy stored in a magnetic field, thus substituting electro-magnetic energy for electro-static, and welds of the butt type up to a cross-sectional area equivalent to ½ in. diameter stock have been successfully made. The complete operation occupies about 0.1 second of time, giving no time for oxidation or excessive heating. The time sequence of events shown in an oscillogram taken during a weld between ⅜ in. copper and steel rod indicates a peak of current of 2600 amperes, an arc voltage of 30, maximum power 60 kilowatts, energy 0.00077 kilowatt-hours, and time 0.094 sec.

# Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

## What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

There is no prize-winner for the January 6th contest. Although we received as many answers as before, not one list was correct. Only one reader guessed query No. 10, yet the answer to the query is found in the first paragraph in the advertisement. Two scales will be given next week, in place of one, to make up for this condition.

**CONTEST FOR JANUARY 27TH ISSUE**

**Contestants are required to write us, stating to which advertisements we refer in this number.**

1—Something that is said to always have been one of the fundamental tools of industry.
2—That if you have an idea it pays to tell about it, especially if you prepare it in a certain form.
3—How to prevent a serious loss in dollars.
4—How to save time, grinding wheels and high speed steel.
5—Something that is said to save money every day it is used.
6—How to learn details about repair work.
7—Something said to be proof against trouble.
8—How to prevent corrosion.
9—Something profitable for both parties.
10—A product said to give absolute accuracy.
11—How to determine your production.
12—A suggestion worth considering.

**These are Correct Answers for List from January 6th Issue:**

1—Heald Machine Co.
2—Brown & Sharpe Mfg. Co.
3—Gisholt Machine Co.
4—Roelofson Machine & Tool Co.
5—Clipper Belt Lacer Co.
6—Canadian Ingersoll-Rand Co.
7—Landis Machine Co.
8—Modern Tool Co.
9—Wisconsin Electric Co.
10—Canadian Driver-Harris Co.
11—Cataract Refining Co.
12—Armstrong Bros. Tool Co.

## Closing Date for This Contest is February 17th

# DEVELOPMENTS IN SHOP EQUIPMENT

## CONTINUOUS MILLER

The Davis & Thompson Co., Milwaukee, Wis., have placed on the market a continuous milling machine that is designed for milling such work as cam shafts, crank shafts, worm shafts, transmission shafts, automobile axles, and any forgings that require milling to length. The machines can also be used for milling small castings such as sad irons, tractor and automobile parts.

As can be noted by the illustration there are two gear housings.

In each gear housing are two spindles which have a micrometer adjustment endwise of 2 inches. This has a locking arrangement to lock the spindles in place after setting to the desired location. These cutter spindles have opposed cone bearings. The right-hand head is adjustable on the bed, the same as a tail-stock on a lathe, and is held by clamps on the bottom of the head, clamping the head to the ways of the machine. This permits milling to length various sizes up to the capacity of the machine. The machine has a single pulley drive and has two changes of speed.

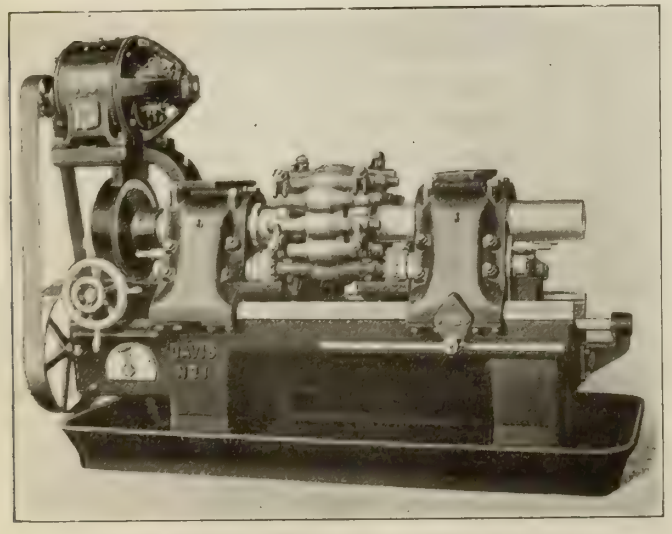
The work mandrel which is supported in each of the gear heads, or spindle housings, is rotated by a bronze worm wheel and hardened steel worm. The different feeds are accomplished by change gears which are located at the back of the machine, and the feed is engaged by cone friction. The lower gear housing which encloses the speed gears is an oil-tight compartment and is filled with transmission oil which insures lubrication to all bearings and gears, while the lubrication is taken care of in the gear heads, or spindle housings, by a large oil reservoir inside of the housing, and the gears run in a bath of oil.

The machine is made to take any desired length within the capacity of machine between the cutters. The fixtures which are made in halves, clamped and keyed to the work mandrel, can be removed very easily. A set of fixtures is made to take each individual class of work to be done on the machine.

In some cases a set of clamps are provided, one clamp holding down two shafts, as shown in the photograph of machine arranged for milling worm shafts, while in a great many cases the machine is equipped with the automatic clamping apparatus for holding round work, small castings, etc.

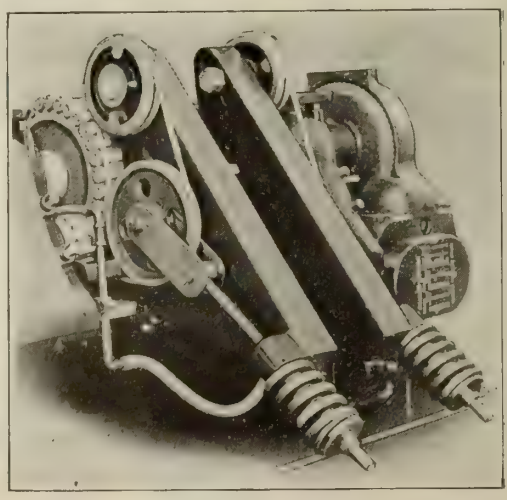
This apparatus as shown in the other view consists of an endless wire cable affair, having two or more cables. The cable is kept taut by the large tension spring shown, and with this arrangement the production on machine is increased, as all the operator has to do is to drop the pieces in the notched jigs, and pick them up as they come around after being milled.

These pieces pass underneath the cable as the table rotates, bringing the work in contact with and by the cutters. This machine has a roughing and finishing cutter which allows the use of a very stiff feed, and the finishing cutter is said to give a good finish even with coarse feed.



When milling castings with the cable arrangement, it is sometimes necessary to make a jaw receptacle for holding castings in place which insures a good path for the cable to travel in, and which will prevent acute bends in the cable. These cables move possibly 20 inches per minute.

## PNEUMATIC ROD CUTTER



The Scully-Jones Co., Chicago, Ill, have developed a line of pneumatic rod cutters that will cut all sizes of rod within their range, without any change or adjustment. The machine is operated at a minimum of 60 pounds air pressure.

It is said to be impossible to break the machine while operating, as it is strong enough to withstand any strain put upon it in shearing rods. The only moving part is the knee-pad, so that no injury to workman is possible.

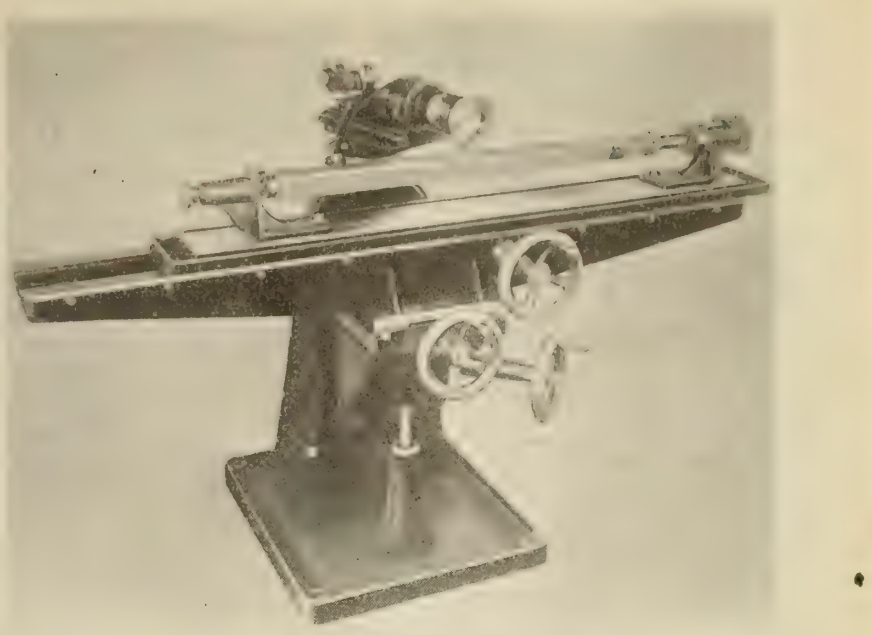
There is practically no expense of upkeep, as the only parts that can wear are the cutters. These are round ring cutters, and as they wear, they can be turned around so as to give each cutter ten new cutting edges. The amount of air consumed in operation is negligible, as travel of piston in the ⅜-inch machine is only ½-inch, and the ⅝-inch machine is only ⅞-inch. Machines can be installed on permanent benches, or

GENERAL VIEW OF THE CONTINUOUS MILLER.

REAR VIEW OF THE FEEDING APPARATUS.

on portable benches on wheels. Air hose can then be run to the machine, enabling it to be taken right to the job.

These machines are adapted for use in all places where rod are cut, such as foundry core-rooms, machine shops, blacksmith shops, bedstead factories, steel mills and bolt factories. The machine will operate without any change, as well with steam as with air. It is made in two sizes, the small machine cutting from 0 up to ⅜-inch diameter, while the larger machine cuts from 0 up to ⅝-inch diameter.



## MANUFACTURING REAMER

That the Gisholt Machine Co., Madison, Wis., have placed on the market a new solid reamer that is adjustable sounds impossible, but here are the details.

The reamer is termed a manufacturing reamer and is made in three body types; the shell reamer, straight shank machine reamer, and taper shank machine reamer. In these bodies the various style blades are interchangeable.

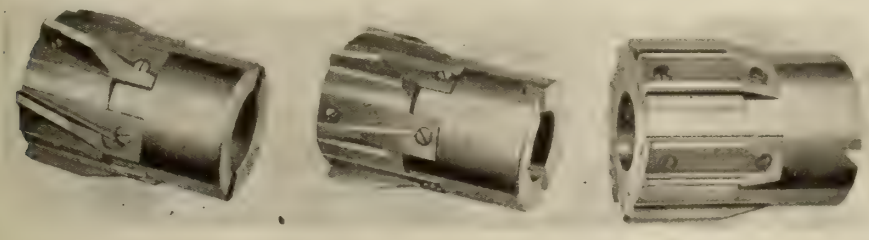
The reamer bodies are made of special steel heat treated. They are milled with a suitable number of blade seats which are wide and comparatively shallow. The blades are of high speed steel accurately ground on the sides and bottom so they not only fit snugly in the blade seats, but are interchangeable. The blades are supported against end thrust by the reamer body itself. The two screws shown in illustration only retain the blade in the slot, and do not take any appreciable strain of the cut.

When worn below size the blades can be packed up with the tin foil underlay stock which is furnished. This adjustment may be repeated several times, and when the blades are finally worn out they may be replaced with new ones, making the reamer as good as new. This construction gives the reamer even more strength than a solid reamer of the same size, with all the advantages and economy gained by adjusting and renewing the blades. It also eliminates the danger of inaccuracy that exists whenever reamers which can be adjusted with a wrench are used on manufacturing work. Reamers of this latter type are frequently useful in the tool room or where a few holes must be specially reamed to fit shafts of varying sizes. On manufacturing work however, duplicate holes measuring within certain fixed limits are required, and as reaming is usually the last operation, the reamer must be depended upon to produce the desired size.

GENERAL VIEW OF THE MACHINE.

## BROACH GRINDER

A single purpose grinder for the express work of sharpening broaches has recently been placed on the market by the J. N. Lapointe Company, New London, Connecticut. This grinder was originally designed and built a number of years ago for use in their own factory. Because of a demand from many users of broaching tools for a machine-tool to easily and accurately grind the small and varying angles of broach teeth, the machine is now being offered to the trade.



It consists of a solid column supporting a vertically adjustable knee. The knee carries a table of which both cross and longitudinal hand feeds are possible. The grinder is furnished with a head and foot-stock, which are mountable on the table for broach grinding and which are removable for the clamping of square broaches and keyway cutterbars. The head-stock is comprised of an index machanism for use when grinding spline broaches and a live center, which is belt-driven from an auxiliary countershaft. The auxiliary shaft is driven by belt off the main countershaft. A three step cone pulley on both shafts gives three possible speeds to the live center spindle on the grinder table.

The table is of sufficient dimensions to grind broaches 64″ long and 8″ in diameter. The sharpening of practically all broaching tools in industrial use is, therefore, within the capacity of the Lapointe grinder.

The grinding wheel itself is carried on a spindle supported by a swivel-head which makes it possible to both grind the rake angle on the back of the broach teeth and to undercut the faces. The head swings on the column of the machine to any horizontal angle and so permits the grinding of teeth machined to any angle to the axis of the broach as well as the grinding of teeth at the customary 90 degrees to the axis. The grinding wheel spindle is belt-driven from the main countershaft. A pair of idler pulleys change the direction of this belt for any angle of the grinding wheel spindle. The whole swivel head mechanism is moved forward and back by a hand lever to put the grinding wheel in contact with the broach teeth, and to remove it from contact. The machine occupies 39″ x 134″ of floor space when the table is extended and stands 47″ high.

## MEASURING INSIDE DIAMETERS

A method of measuring the inside diameter of plain ring gauges has been developed by the United States Bureau of Standards, employing two steel balls the sum of whose diameters is slightly larger than the nominal inside diameter of the ring to be measured. The ring is laid on a surface plate and the larger ball placed in the ring; the smaller one then rests against the inside of the ring and on the larger ball. The difference in vertical position between the upper surfaces of the two balls is determined by means of a micrometer attachment. This dimension is easily converted into the vertical distance between the centres of the two balls. The value thus obtained forms one side of a right-angled triangle whose hypotenuse is the line joining the centres of the two balls and whose base it is desired to determine. Knowing the vertical side and the hypotenuse, it is possible to calculate the length of the base, which, added to the radii of the two balls, gives the inside diameter of the ring.

## Make the Most of It

THAT employers should try to make out of the present situation in industry conclusive proof that their men do not need added protection in the way of unions is an idea brought out by J. Harvey Williams, president of the J. H. Williams & Co., Brooklyn, and known better to this country through the company's plant at St. Catharines.

Mr. Williams, in a statement regarding labor conditions, makes it plain that he considers the retailer responsible for holding back from the consumer the benefit of reductions that have been made in the prices of commodities, and in this way making it harder to readjust wages.

Mr. Williams is right when he claims that the manner in which readjustments to new levels are made now will have much to do with future industrial relations, adding "for just as it is the reactionary employer of the past century who is chiefly responsible for the origin and growth of the pernicious features of some of the trades unions in this country to-day, so the employer of to-day by a liberal and just attitude has a greater opportunity than has ever been presented to him in recent years to demonstrate to his men by his acts and by his understanding that additional self-protection in times of prosperity is merely a waste of their hard-earned money—and that is what it should be if the spirit on both sides is right."

If an employee, now that work is scarce, and the advantage rests with the factory, has cause to feel that the screws are being clamped on him to the point of oppression—as a competent worker he is finished.

Henceforth he will have two jobs, one to make enough showing to hold on to what he has, and the second will be his preparation to hit back.

He will come to the conclusion that his safety lies in his membership in a union and not in the justice of his employer.

This is a lamentably poor time for employers, superintendents or those in charge of employment to be working out a long-nursed grudge.

You have heard it—something like this: "For the last five years the men have run this shop while I financed the thing. Now I am going to show them who's running this place."

Don't work along these lines. Remember paying up a back score is also determining the future atmosphere of your shop.

If your business has been very good during the last few years, let go of some of the surplus and provide as much work as possible.

If things are still going fairly well, don't be too keen to put the axe into the wage list.

The employer has a good chance now, even in times of uncertainty, to spike the guns of the labor agitator.

## Canadian Machinery and Its Readers

CANADIAN MACHINERY has been running a series of questions recently with the idea of encouraging the reading of the advertising pages of this paper, and the results are away and beyond anything that could be hoped for. This week the first letter coming in was from Sydney, N.S., and the next was from Vancouver, B.C. Here are a list of places from which replies were received in the last few days, taken at random from the list: Villeray, Que.; Yarmouth, N.S.; Fredericton, N.B.; Welland, London, Lunenburg, N.S.; Sarnia, Chicoutimi, Que.; Edmonton, Winnipeg, St. John, N.B.; Niagara Falls, Hartford, Conn.; Euclid, Ohio; Kitchener, Prescott, New Liskeard, Copper Cliff, Guelph, Sault Ste. Marie, Port Hope, Brandon, Man.; Westville, N.S.; Toronto, Peterboro', Halifax, Sydney, Dundas, Penetanguishene, Kenora, Sycamore, Ill.; Hamilton, Montreal, Brantford, Gull Lake, Sask.; Rockford, Ill.; Woodstock, Sherbrooke, Port Arthur, Galt, St. Catharines, Cleveland, Ohio, Fergus and Elmira.

The answers show that readers are going very carefully into the matter, some of them often going to the trouble to point out that other ads. conform very closely to the ones mentioned in the list.

It proves beyond a doubt that the advertising pages of Canadian Machinery are being read very thoroughly by the mechanical world of the Dominion.

We have often been told by our readers that they found a great deal of useful information in the advertising pages, but the manner in which intelligent and carefully-worded replies are coming in from all corners of the Dominion and many times from mechanical points in United States, shows beyond doubt that readers are paying attention to the advertising pages of Canadian Machinery in an unusual way.

## A Mechanical Wonder

THE Bell Telephone Co. are putting in a new pay-phone which hands the money back if the party calling fails to get service. It is an ingenious piece of mechanism and goes to furnish further proof that the world is indebted to the skilled mechanical mind and hand for many things.

This new machine should be built with a fairly strong digestive system, as past experience in pay-phones shows a crop of punctured coins, bogus money, buttons, washers, tobacco stamps and a steel washer that was much in evidence when airplanes were being made.

If this new machine can stomach all these missiles instead of honest-to-goodness money and still courteously hand out change to dissatisfied customers, it will be nothing short of mechanical conformity to the Golden Rule.

## Just a Nasty Burn

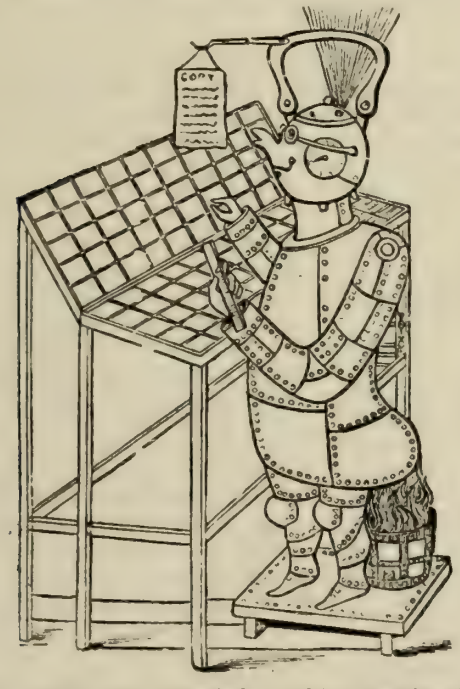
ONLY a few days ago a workman from an outside plant was engaged to put something in order on a process where hot metal was in use.

Another workman carelessly dropped a block of metal in the melting pot. It was wet in spots with the result that a good-sized splash followed, in which the outsider had a nasty burn on his wrist.

He asked if there was a first aid box as he wanted to have the wound attended to at once. The answer was that the firm wasn't very strong on "this new-fangled stuff."

And so the mechanic had to do the best he could, working away with a nasty open burn on his wrist and in a place where he was apt to pick up something that might cause trouble afterward.

A little first-aid box is not in the "new-fangled" class.



It is as necessary around the shop as an insurance policy, a cost system and a payroll.

And yet it is astounding to consider the number of fairly large firms where little attention is paid to this matter.

## It Can't Be Done

WHY is it that so often a step in advance in any mechanical contrivance is heralded by a storm of "It can't be done" comment? It may be that there is not so much of this done now as some years ago, as we are now living in an age where mechanical ingenuity knows few limits.

But take the case of continuous feeding to an automatic machine as an example. The old method was to loosen the chuck, take out one piece and insert another and so on.

The old hands that attended to this considered that at times they could attain a speed that was pretty close to continuous feeding, but in reality it was a long way from it.

But the change came. Now the automatic has its magazine. The work is loaded in the magazine and is always kept loaded the same as a repeating rifle. As one piece is completed it drops out, falls down a chute into a box, while the other piece drops into place and is gripped by the chuck and machined.

The new order of things IS, while the old way WASN'T.

On this page we have an example of so-called wit of years ago when the old-time printer was telling the world that there was no chance of any person ever building a machine that would set type. It used to run like this: "Imagine a machine that can walk around the office from one case to another and set type." There was always a good congregation for any such talkers and they would settle to their own satisfaction that the thing simply could not be done.

The artist in this case has been somewhat of a satirist and labelled his picture "The Great American Steam Type Setter." This was some fifty years ago. If this old boy could walk into any printing office to-day and watch the working of the linotype he would see where the "Impossible" chorus had been all wrong again. He would see one of the most complicated and yet one of the most possible machines ever turned out. He could at once recognize just what mechanical movements can be done with a properly timed set of cams. He would have seen also that he was on the wrong set of rails when he was spending his time in ridicule when others were spending their time in doing the thing.

This same thing is happening in every line and is not solely the child of the machine shop or of the mechanical world.

There are always plenty to view any situation, particularly if it is difficult and likely to call for extra exertion, and declare "It can't be done."

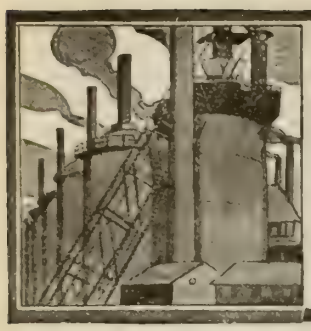
It does not require much courage to take this attitude —just a mental assent to an easily-arrived-at conclusion.

But some person is sure to come along sooner or later who has not been steeped in the "can't be done" brew and he goes ahead and does the thing.

## Eureka! I Have Found It!

THE excitement appertaining to the fearful and wonderful adventures of the heroic balloonists having somewhat subsided, the enterprising representatives of the daily press have been forced to look around for something of interest for their readers.

The search has resulted in nothing less than the discovery of what electricity actually is. This is not the first time it has been discovered, for only recently we were regaled with the story of a twelve-year-old boy who ran a four and a half horse power motor boat engine for a number of miles without any fuel except the circumambient atmosphere.



He explained that his real motive power was electricity drawn from the atmosphere.

Yes, just that. The present discoverer is said to be no less a person than Dr. Frederick Klein, a noted chemist and research worker in cancer problems. Dr. Klein explained his discovery to a reporter in the following simple language: "The average chemist and the average scientist figure on the bi-valency of oxygen and only lately has research proved that oxygen is also 4, 6 and 8 valent. It is in the valency of oxygen and its ratio that the possibilities lie for bigger things for the future."

Dr. Klein states that all that is required is for a group of varied scientific minds to be brought together and work out the remaining part of the problem and the question of light, heat and power is solved forever.

Coal will be an article only for exhibition in the museum. The ultimate consumer will have a storage tank on top of his garage, from which he will draw his supplies of power, heat and light for household use and motive power for Lizzie.

So far we have not noticed any serious drop in the price of coal, but we would advise any of our readers who have shares in collieries or the Standard Oil Company to get out while the getting is good. This is truly a wonderful age we live in.

# MARKET DEVELOPMENTS

# Very Little Change is Shown This Week

## Prices in Several Lines in the Steel Market Are Lowered in the Warehouses—New York List Withdrawn Because Prices Were Considered Too High—One Dealer Looks For a Very Good Season's Business.

NOW and then one finds a dealer who has become an optimist. It is not claimed that this class is by any means large, but it is on the increase. A dealer handling supplies, new and used, for builders and contractors, reports that he is going to have the best season in his history.

There is more consistent work being done right now in the selling business than has been witnessed in the Canadian field for months, if not in years. Wherever there is any business showing up there is certain to be a small army of salesmen. A certain amount of hanging-fire business is being closed up in this way now. Prices of machine tools remain unchanged and a New York buyer having a fairly good list in the market withdrew it because the dealers had made no change in their prices. There are no indications that makers are going to depart from their present schedule of prices.

In this district there have been some reductions in the steel and iron warehouses. Sheets are down a little and there is a tendency to give pretty close prices on this item in order to get cleared out of present stocks. It cannot be claimed that there is anything in the nature of a price-cutting policy being carried out. Buying is still being done in very small quantities and stocks are very light in manufacturers' warehouses.

A certain amount of business is being given out by the automobile makers and the volume of this is likely to increase as time goes on. The principal thing, according to the trade, is that a start shall be made toward operating the plants.

The scrap metal trade is still very flat, but there seems to be a pretty well-grounded feeling that the bottom of the price list has been reached and that any kind of a buying movement would result in prices becoming firmer almost instantly.

## LOOKING FORWARD TO BETTER CONDITIONS WHEN SPRING OPENS

Special to CANADIAN MACHINERY.

MONTREAL, Jan. 27.—The optimism that dominates nearly every phase of industrial activity is the one encouraging note that features trading at the present time. Some reports indicate a slight betterment in business carried on, but in general the different markets continue in a more or less listless condition, but with sufficient future inquiry to give the impression that early spring activities will be on a larger scale than those of the past few months. The tendency is shown in many quarters to establish new working conditions to better combat the declining prices on many staple commodities. Much of this is being done with the reluctant co-operation of workmen in the plants; yet, while realizing the necessity of meeting the manufacturers half-way, they are still confronted by the fact that many necessities of life are still at war levels, and in some cases even higher.

This fact tends to delay any marked improvement in general business conditions. "One of the essential factors," said a business man here, "in re-establishing a healthy state of commercial and industrial activity, is a more widespread recognition of the necessity of conforming with the needs of the time, in accepting some of the losses incidental to adjustment to lower levels in the cost of manufacture. Many merchants, in domestic lines, are still reluctant to dispose of stocks on a replacement basis and this attitude is extending the time when business will be returned to a normal footing. Of course, we steel interests are not affected, directly, by what transpires in the retail trade, but if individual buying is restricted, production is necessarily curtailed, and with factories operating light, their requirements are proportionately reduced."

### Hard Work Selling Steel

Statements to steel dealers here are to the effect that business is proceeding quietly but showing no marked improvement. "We do not think that prices will recede much further as those now quoted are practically rock-bottom. There may be some slight reductions by independent producers, but not sufficient to have any material influence on the general situation. Railroads have been putting off buying, but it is expected that a change in this respect will soon take place and when the buying movement does commence the market will strengthen and prices become even firmer than they are at present." Speaking on the decline that has taken place on the English market, the dealer continued:

"Prices over there have been so much higher than those in the States that they can well afford to knock off considerable without in the least affecting the market here. For some time back, steel could be shipped from Pittsburgh and laid down in England at less than it could be purchased at English mills." Salesmen are having some strenuous times in persuading purchasing agents as to the advisability of buying now. Conservatism is still the policy of many consumers.

**Special Efforts Produce Sales**

"It is only by consistent efforts on the part of our salesmen that we can report a week of fair business. It has been shown that more energetic effort has resulted in slightly better business, but this does not signify that next week will give the same results, for buying without using only means that their stocks are increased that much. What is needed is greater activity, and it is only this that will assure a steady turnover. We are selling few heavy tools, the greater number of sales being in the smaller lines." This brief statement appears to be typical of machine tool conditions here. One dealer, who remarked that business was very quiet, stated that he had not received an order nor an inquiry for two consecutive days, and it was only the compiling of the stock inventory that kept them engaged. Despite this fact, however, they are looking forward to better business before the winter closes.

**Old Material Still Inactive**

Little can be said in favor of the old material situation, as business is more or less of a nominal character, with dealers going to their offices more as a matter of habit than for the transaction of business. It has come to the point where the dealers are as anxious to learn the trend of activity as any other person, for the usual greeting on entering the office is: "How do you find things yourself?" Mutual confidences usually dispel any pessimistic tendency, but throw little light on what will develop in the immediate future. "As regards prices," said a dealer, "it is difficult to give definite quotations as these will vary according to the sale, but those you are quoting are, on the whole, equivalent to those we are paying. The non-ferrous metals might be shaded a little but steels are fairly firm."

## SOME PRICES ARE SLIGHTLY LOWER

**But Business Has Not Shown Any Improvement Since the Turn of the New Year**

TORONTO.—Those who were predicting that a business recovery was going to take place at the first of the year must know by now that they were wrong. In some lines the prediction was doomed from the very outset, as January is never a very large month.

The machine tool trade is not making many sales, but the salesmen are working harder, and are bringing in business that would not have come along in the ordinary course of events. One firm told this week of having the order for several machines ready to sign, but the buyer was holding off on a matter of price. He seemed to be positive there was going to be a reduction made in the price of machine tools, and no amount of arguing will convince him that we should stand on our price. As a matter of fact the dealer handling this sale has nothing to do with the price of the tool, but there is a nice order hung up waiting for the buyer and seller to come together and close the thing out.

A fair trade is being carried on in used machines, and a number of these have been rebuilt during the past season. The price of new tools is quite an inducement to turn to this field.

**Some Firms Starting**

Some of the automobile concerns are getting under way now, and during the last few days they have placed some very good orders for parts. Some of the salesmen who were down that way looking for a share of the business report that there was the greatest gathering of salesmen seen at one place at one time after one piece of business that had been recorded for some time.

Some of the locomotive firms have bookings that will help to keep some trade moving. The question has been raised again regarding the drawback on export of Canadian material. For instance, one firm contracts with a foreign order for a certain number of engines, or cars, or anything in that line. When these are exported the firm is entitled to receive a drawback of 99 per cent. of duty paid for the material in case it was brought into Canada. If a Canadian manufacturer supplies materials for this manufactured article he is not entitled to any consideration in having to compete with the American manufacturer. If a Canadian manufacturer, for instance, needs nuts, bolts, etc., for an article to be exported, he can bring in United States material free of duty by reason of the 99 per cent. drawback on the finished article. The explanation of the tariff department of the Canadian Manufacturers' Association is that the tariff here is arranged this way in order to allow the Canadian manufacturer access to the cheapest source of supply, otherwise he could not secure the business.

**The Steel Market Easier**

Several prices are down a little in the steel market, and there is more or less of a tendency on the part of the dealers to shade their prices in order to land the business. It cannot be charged that there is anything approaching a cut-rate business going on, but the tendency toward "bargaining" is more marked than it has been for some time past. Black sheets 28 gauge are selling at 7.50c per pound, while blue annealed have been marked at 6.50. Premium 28 galvanized sells now at $10, and 10¾ at $10.40. Quarter-inch plate is quoted at $5 base; cold rolled shafting at $7 base.

**Small Tool Sales**

There are some rumors regarding cutting of prices in the Montreal district in small tools, but nothing general is being done in this line. It is impossible to keep dealers lined up at all times to adhere to standard prices, but for the most part there is very little price shading being done in any district now.

One thing is certain, though—salesmen are working harder for a given amount of business than they have been for some time past. The sales manager

## POINTS IN WEEK'S MARKETING NOTES

**One dealer in equipment for contractors states that from inquiries in their hands at the present time they are going to have the largest years' business they have ever done.**

—

**Several reductions have been made in the last few days in the prices of some lines of steel in local warehouses, and there is a tendency at times to even do better than the quoted prices, but this has not developed into anything like a price cutting campaign.**

—

**The scrap metal market remains very inactive, although the belief seems to be fairly well established that the bottom of the market has been reached and that any buying movement will result in firmer prices.**

—

**Some of the large automobile plants expect to start work shortly, and are already placing a certain amount of business for parts.**

—

**One large list of machine tools that went to the New York market was withdrawn because the purchaser insisted on lower prices.**

—

**Dealers and salesmen generally report that there is more competition for business now than there has been for years, and every order that comes on the horizon brings forth a regular procession of salesmen.**

—

**Pittsburgh dispatches claim that there is no improvement in the steel market as far as any business is concerned, and they further point out that January is not the month to expect such a movement.**

—

**Some of the United States railroads would buy more equipment if it were not for the failure of the government to pay them their guarantee under the railroad act.**

—

**Machine tool plants in the United States are for the most part closed down, or running on very short time. Canadian makers seem to be faring better than those across the border.**

of one of Ontario's plants was telling Canadian Machinery this week that he had spent two or three days at the large auto shops trying to see what he could bring home in the way of business. He had succeeded in landing a nice share of the business, "but," he stated, "I never did see such an assortment of salesmen before, and I have been in the selling business for a good many years. Of course the orders being placed just now are not as large as usual, but in this case it looks as though the auto plant in question is getting ready for operations on a very fair scale."

Another salesman representing a small tool firm, has just made the trip through Western Canada to the coast, and reports conditions quiet in that field. "It is surprising where the business comes from in the west," stated a representative of this company, "to go through it one would never think there would be much demand for our line outside of a few industrial centres, but the figures from this field for the year just closed are well over the estimate we had set for this field."

# THE PREDICTED REVIVAL DID NOT COME WITH THE NEW YEAR

Special to CANADIAN MACHINERY.

PITTSBURGH, Jan. 27. — There are lacking even the rumors that usually spring up in a dull season that the steel market is improving, which shows that the situation is particularly unpromising. Of course, the prediction made in December, that there would be improvement immediately after the turn of the year, has gone by the boards, as anyone should have expected it would since it is not natural for the steel market to improve in January. March is a favorable month for that, and there is still a possibility that there will be improvement at that time, but this is no more than a possibility. The common prediction is that there will be no great improvement until after the summer is over, but the predictions are indefinite in that they do not assert that there really will be great improvement at that time.

It remains the common view that all that is wrong with business is that a general readjustment in commodity prices and wage rates has to be made, but if that is all that is requisite there ought to be improvement within a very few months since the deflation is already quite extensive. It is true that thus far wage reductions have been exceptional rather than general, but it does not follow that extensive wage reductions will not be made within a couple of months. Many manufacturers, convinced that wages must be reduced, have simply been waiting until there has been a spell of idleness, in order to make wage reductions more acceptable. In the steel industry the latest reductions are those of the Inland Steel Company and the Steel & Tube Company of America, both in the Chicago district, the reductions amounting to about 20 per cent. The Pittsburgh and Youngstown districts have seen scarcely any reductions. The independent ore interests in the Lake Superior ore region are reducing wages 15 per cent. This, of course, is in anticipation of the expected reduction in Lake Superior iron ores for the season of 1921, the common guess being that there will be a decline of $1 a ton from the 1920 season prices. This would put ore prices back to the level of the 1919 season, making Mesabi non-Bessemer ore $5.55 at Lake Erie docks.

The Steel Corporation shows no signs of contemplating any wage reductions in any of its operations, and the trade believes that while the corporation will eventually reduce wages it will only do so after all the independents have taken action.

In some quarters a feeling is now arising that there may be something more wrong with the business than merely the need of price and wage readjustment. Increasing attention is being paid to the fact that many large business interests, supposedly in sound condition and believed to have made very large profits in the past few years, are borrowing money at high rates of interest, equivalent to between 7 and 8 per cent., on notes or on short term bonds, and the question is why this should be necessary if things are as they seem to be. There is satisfaction, of course, that there have been so few business failures. At the same time great credit is given to the operation of the Federal Reserve Act, and it is said that if this system had not been established there would have been many failures. However, the proper analysis of the facts seems to be that even though failures and a regular panic have been averted the fundamental conditions must be bad, more or less, or there would have been nothing to avert. It must be understood that when borrowings at high interest rates are mentioned the iron and steel industry is not referred to. This industry is perfectly sound financially and has no occasion to borrow money. It does a cash business and really got the profits it was making. Its inventories of raw and partly manufactured material are relatively low and it has no finished goods in stock.

### Production

The rate of steel production has a generally declining tendency but the rate is very slow, because the Steel Corporation maintains its rate and the independent mills reached such a low operating rate in December that further decreases in their rate cannot make much difference. As noted in last report the Steel Corporation is producing steel ingots at about 21,000,000 tons a year and the independents at about 7,000,000 tons, which makes a rate for the whole industry of about 53 per cent. If the independent rate should be cut in half that would merely bring the rate of the whole industry down from 53 per cent to 47 per cent.

The independents are operating intermittently. A mill closes for a week or two and then resumes in part on an accumulation of orders, while another mill may close to enable orders to accumulate. The next important change will occur by the Steel Corporation's production decreasing. The Steel Corporation entered this year with a large volume of business on books. It is not remarkable that the corporation's customers should "stick" but it is remarkable that they should continue to take shipments from week to week at such a high rate. How long the present operation will last is problematical. Many customers may say that they want the material eventually, but desire that shipments be made at say one-half the former rate. If there is no change in this respect it may be said that the specifications now on books would enable the corporation to continue at practically its present rate for a couple of months without the aid of new business while if new specifications and orders should keep up at the present rate the time would be prolonged. Afterwards the corporation's production would gradually taper off. As to the independents there is no indication that they will be able to run much better than at present until there is a general buying movement, and that is not expected for the near future.

### Prices

There are the usual rumors of price cutting of steel products, in most cases quite indefinite. The condition is worse than that of orders being booked at cut prices, the fact being that orders are not booked at all. The mills are getting only a little business and what they are getting is chiefly, in the case of independents, in the form of releases on instructions previously given to suspend shipments. In the case of the Steel Corporation, the business being booked is either from regular customers or, in a few cases, from consumers who were not corporation customers during the 1920 flight of prices, and resolved that whenever the opportunity should occur for them to get on the corporation books they would embrace it.

Eventually a buying demand will develop and then there will be real price cutting to find the bottom, or basis on which business can proceed. That time may be far in the future.

## REFUSED TO BUY WHEN SHOWN PRICES

**New York Machine Tool Market Is Not Experiencing Any Recovery Yet**

Special to CANADIAN MACHINERY.

NEW YORK, January 27.—No tangible improvement in the machine-tool situation is to be noted. It is true that there have been more inquiries in the past week, but orders are not being placed. The reason for lack of buying in some instances is the expectation of buyers that prices are coming down. The Otis Elevator Company, which about ten days ago issued an inquiry for about twenty machines, informed sellers after quotations had been received that it would await "better prices." Similar action was taken by one of the railroads, which had inquired for about a half-dozen machines.

Some of the railroads are in a mood to buy a moderate quantity of new shop equipment, but are held up by the failure of the government to pay them their guarantee under the railroad act. In fact, some of the roads are having difficulty in meeting their current bills. It is not regarded as likely that they will be able to do much buying before the middle of the year.

Many of the machine-tool plants remain closed down, or virtually so, while even those in the best position are operating at only a small percentage of their normal rate.

The meagre amount of buying in the new year has been a source of disappointment to those in the trade who quite confidently expected that an improvement in conditions would begin to make itself evident about this time. A disturbing element is the number of new machines which are being offered for sale at prices less than the manufacturers' selling prices. Some of these machines so offered were originally purchased for export and the orders were cancelled before the machines left New York. Consequently the export companies are trying to get rid of them, even at a loss.

## CUTTING PRICES IN BRITAIN NOW

**London—The steel makers along the northeast coast adopted a policy of drastic price-cutting, the reductions ranging from £2 per ton for rails and ship plates to £4 for billets.**

**It is stated in steel circles that the reductions bring a majority of the selling prices below the actual cost of production. The action of the northeast coast men follows that of the Scottish steelmakers in making a reduction of from 20 to 27 shillings per ton.**

**The drastic cutting in prices is said to have been necessitated by increased foreign competition, which has virtually stopped demand for the dearer home-made articles.**

## PLANTS LIKELY TO START AGAIN

There are some indications that plants in the automobile industry are not going to remain closed much longer. In this district there is little improvement and very few employees are working in the plants.

Car makers are begining to realize that if they are going to be in the running for this year's business they must get going in the very near future.

Speaking to a representative of a company handling sprinkler insurance, Canadian Machinery learned that several of the largest companies in the automobile business, which have been closed for some time, are not taking advantage of the shut down clauses in their policies. Some of these automatically allow a thirty-day shut-down, after which it is necessary to make application and take advantage of special provisions in the policy. This representative had been visiting a number of these places, and found that in the case of the larger ones there was no intention to take up the clauses regarding a shut-down of the plant for more than thirty days. There can be only one meaning to this, viz., that the plant is going to operate.

## TRYING TO PUSH BRITISH GOODS IN CANADIAN MARKET

THE Montreal branch of the Canadian Association of British Manufacturers held their annual meeting at Freeman's Hotel on January 21. Following the luncheon the business was opened by the address of the retiring president, H. W. Weller, who outlined the work accomplished during the past twelve months, emphasizing the better progress that had been made as a result of the closer co-operation of the two branches, and the added interest that had developed in all activities of the association. Through the personal efforts of G. T. Milne, H. M. Trade Commissioner during the early part of 1919, and the enthusiasm of the officers and members since that time, much has already been achieved by the organization for the furtherance of British trade in the Dominion of Canada. Considerations have been obtained from the Government at Ottawa, regarding the customs valuation of invoices, that has simplified the work of importers and exporters. Recognition has also been given to the request for tariff modifications and steamship concessions — conditions that have assisted materially in promoting British trade. It was stated that negotiations were under way with kindred associations in other British Dominions for a permanent representative in London, with an office for the use of the members of the different associations.

Brief addresses were given by G. A. Marshall, Capt. John Harris and W. E. Bunny, president, vice-president and secretary, respectively, of the Toronto branch of the association. Emphasis was laid upon the necessity of every member working in accord with each other, and also co-operation with the branch officers, and likewise between the two branches, so that the work of the entire organization would be co-ordinated and maximum efficiency and benefit attained.

Owing to the fact that, henceforth, the government of the association shall be vested in the Supreme Council, the constitution has been revised, and the proposed draft was read to the members for their criticism and approval. Without a dissenting voice the draft, as prepared by the committee in charge, met with the unanimous approval of those present, and its adoption was decided on, pending the favorable consideration of the members of the Toronto branch, the annual meeting of which will be held on January 28.

The Montreal branch, at present, has two well organized trade sections, that of textile and steel, and it is expected that other sections will shortly be formed to accelerate the interest in other branches of trade development. It was likewise proposed that regular monthly meetings be held, as it was felt that, in this way, greater progress could be made and a more friendly spirit amongst the members in general created.

The local council for the ensuing year was elected at this meeting, and is as follows:

1st vice-president—F. I. Spielman.

2nd vice-president—J. E. Ritchie.

Executive Council—Allan S. Bain, St. Clair Tilley, Harold Brooke, W. T. Evans, H. W. Smythe, D. W. Clarke.

**Want Material.**—This paper can furnish the name of a firm wanting to get information about a supply of strip steel ¾-inch x 12 gauge, 1½ inch x 10 gauge, 15 carbon.

Ray W. Wolvin, president of the Dominion Iron and Steel Company, returned from London on January 24, where has been conferring with the directors of the British Empire Steel Corporation in connection with the consolidation of Canadian steel and shipping interests.

C. H. Handerson, advertising manager of Cleveland Twist Drill Co., 1242 E. 49th St., Cleveland, has gone to the Union Trust Company as advertising manager. Mr. P. C. Handerson, his brother, has replaced him at the Cleveland Twist Drill Company. The Union Trust Company is a consolidation of six large Cleveland banks and is the largest banking unit in Ohio.

## Pig Iron Markets

The trend of the pig iron market is toward still lower levels. Valley No. 2 Foundry has been offered at $30 and Basic at $29. Pig iron buying has improved to some extent in the Philadelphia district. About 5,000 tons were sold during the past week.

The Chicago market is exteremely dull with melters disinterested and only occasional purchases being made of carloads. Little new business is being done on the Cleveland market, although inquiries are declining and one lot of 1,000 tons for the next 30 days has been quoted at $30 base Valley.

Altogether the sales during the past week on the New York were not greatly in excess of 1,000 tons.

The pig iron market at Pittsburgh has been more active than for several weeks past. It is understood that one sale has been made of 1,000 tons of No. 2 foundry at $30 valley.

The Boston market shows practically no business. Many of the stacks of furnace interests supplying this district have blown out.

The Buffalo market shows a wide range of prices. Sales of No. 2 foundry 1.75 to 2.25 silicon are recorded all the way from $32 to $35. It has been stated on reliable authority that considerable amounts of No. 2 have been sold at $30. A maker that has figured prominently in the resale market reports last week as the heaviest in about three months. About 4,000 tons of foundry of all grades were sold. No. 2 plain sold at $32; No. 2x 2.25 to 2.75 silicon at $35.25 and No. 1x 2.75 to 3.25 at $35.

The St. Louis market reports a total absence of business and the attitude of consumers is discouraging, as they will not do business until prices are reduced.

## Scrap Metal Market

Some dealers believe that the scrap metal market has at last reached bottom.

The Chicago market during the past week has shown very little change. Actual prices are difficult to quote at present. Scrap consumers for the most part are remaining out of the market. Rail road offerings are moderate. Prices which last week were considered as being rock bottom have been lowered several dollars and the demand is so light that even the low prices fail to move much tonnage. Heavy melting steel is down to $9 and mixed borings and turnings have dropped from $7 to $5.50.

The New York scrap dealers report a better inquiry for wrought material. More interest is being shown by the rolling mills and this has resulted in a greater firmness in prices.

The Pittsburgh market is exceedingly quiet. The usual industrial sources of supply are not operating so there is very little tonnage appearing. One of these sources is the automobile industry, which furnished large tonnages of turnings and borings for the Pittsburgh and valley territories.

On the Buffalo market one local mill is taking tonnages of scrap on suspended old orders, and is contracting for several new lots in small quantities. They are offering $15 for heavy melting steel.

Dealers in the St. Louis market are beginning to purchase scrap, and the heavy railroad offerings have brought forth better bids. Heavy melting steel and shoveling steel were marked up 50 cents, the former being quoted at $14 to $14.50. Rerolling rails have risen from $15 to $16.50 to $17.

The scrap market continues to lag in the south. Hope is expressed at Birmingham that a turn for the better will take place soon. Quotations remain practically unchanged.

---

What is claimed to be the most powerful wireless transmission station in the world was opened recently at Croix-d'Hins, eighteen miles from Bordeaux. The station, the aerial of which has eight pylons 850 ft. high, is designed to reach, in normal circumstances, any point in the world, including New Zealand, while North and South America will be within its effective radius, however bad the atmospheric conditions.

# GET THEIR NUMBER

Numbers 1 to 16 represent one of the Geometric Self-opening and Adjustable Screw Cutting Die Heads, Solid Adjustable Die Heads and Adjustable Collapsing Taps.

No. 1—Class N-L Pipe Tap. Made in sizes from ¾" to 10" inclusive. Represents tapped diameters of 1-1/16" to 13-1/2" straight threads, and 3/4" to 12" standard pipe threads.

No. 2—A Geometric Brown & Sharpe Taper Turning Tool.

No. 3—Style C Die Head, Lever Trip Type. Recommended for cutting threads of short length.

No. 4—Two-Chaser Class U Tap, for tapping fine pitch threads, ranging from 1/2" to 1-5/16" diameters.

No. 5—Style D-D Die Head for Cleveland Automatic. Floating and tripping adjustment features make this a very desirable Die Head for these machines.

No. 6—Adjustable Hollow Milling Tool. The cutters are readily removed for sharpening. Micrometer adjustment makes quick and easy settings.

No. 7—Rotary Die Head. Recommended for live spindle use.

No. 8—Class P Tap, Plate Trip Type. Used wherever tripping plate can come in contact with the work.

No. 9—Style D Die Head. For general use where thread is not too short. Made in sizes from 5/16" to 4-1/2" inclusive. Represents threaded diameters of 3/32" to 4-1/2".

No. 10—A 1/8" Style D Die Head, the smallest size. Cuts down to 1/16" diameter thread.

No. 11—Taper Threading Die Head, with inside trip and roughing and finishing attachment. Recommended for coarse pitch taper threads.

No. 12—Style C Die Head, Inside Trip Type. For cutting short threads where the length of thread is best controlled by an adjustable internal gauge or stop.

No. 13—Style D-D Die Head, with roughing and finishing attachment. Flanged for Warner & Swasey Turret Machine.

No. 14—Style C Die Head, Pull Off Type. For cutting threads on light work.

No. 15—Style C Die Head for Brown & Sharpe Automatics.

No. 16—Solid Adjustable Die Head with floating shank, for Gridley Automatic.

These Die Heads and Taps are adapted for use on the turrets of practically all makes of hand and automatic screw machines and turret lathes.

By using extra sets of Thread Chasers, each tool can be used for a range of diameters; the larger the size of tool, the greater the range.

Make screw thread cutting the most satisfactory operation in your Shop. Let a GEOMETRIC show you how.

## MEETING IN MONTREAL TO ORGANIZE THE WELDERS THERE

WORKING in harmony with a meeting held recently in Toronto, relative to the organization of a Canadian Welding Society, A. M. Barry, manager of the St. Lawrence Welding Company, of Montreal, called a special meeting of those in this district interested in the movement. The meeting was held last Thursday at the Windsor Hotel, and although the notice given was necessarily brief, a goodly number of firms were represented. Those present, beside Mr. Barry, were:—A. McMillan of the Canada Carbide Co.; C. Royer, of Welding and Supplies, Ltd.; A. F. Dyer, welding supervisor of the G.T.R. at Pt. St. Charles; P. Reynolds, Supt. of the St. Lawrence Welding Co.; W. G. Cole, of the Advance Machine Works; W. P. Bennet, of the Canadian Welding Works; T. Jones, works-mgr., of the Canadian Vickers Co.; H. P. Booth, plant manager of the Montreal Locomotive Works; D. Buttler, L'Air Liquide Society; and J. H. Rodgers, of Canadian Machinery.

In opening the meeting Mr. McMillan, the chairman, who, with Mr. Barry, had been present at the Toronto meeting a couple of weeks ago, outlined to those present the objects of the proposed association and the initial steps that had already been taken at the inauguration meeting. A copy of the proposed constitution had been received and the different clauses and sections were discussed. The meeting was unanimous in its decision that an association, well founded, would be highly beneficial, not alone to those associated with the society, but to the welding industry in general. It was the opinion of those present that the science of efficient welding was not making the progress that it should, and that, in some instances, great harm was being done and development retarded, due to the inefficiency of much work carried on by inexperienced operators, the results in such cases often giving a temporary "black eye" to the better progress of the welding art.

It was stated by Mr. Barry that the Government had the question of welding standardization under consideration, and it was only a question of time before they would be faced by certain regulations governing the practice of welding in general. It was therefore thought that a well organized body of experienced welding men would be better able to cope with the situation and at the same time present a united front in protecting the interests of the craft, and likewise provide better facilities for disseminating knowledge amongst its members.

While the proposed constitution, on the whole, was favorably received by the Montreal gathering, several clauses were the subject of criticism and discussion. One of these was that in regard to standardization in welding practice. As this was too wide a subject to be passed over lightly, and at such an early date in the activities of the association, it was deemed advisable to instruct the Montreal delegates attending the forthcoming meeting in Toronto to obtain further enlightenment in regard to the question of "standardization." Mr. Dyer of the Grand Trunk, remarked that the practice in railroad shops was, invariably, carried out under specific regulations, but that the system on one road differed from that on another, and sometimes, to a great extent.

Exception was taken to the "head office shall be in Toronto." Due to the fact that the proposed constitution called for the election of officers by letter ballot, it was not clearly seen how an arbitrary ruling could be made in this connection, as it was possible that the election of officers might result in the president and secretary being elected from points outside of Toronto. However, the Montreal interests are determined to work in harmony with those in Toronto and other centres, so that this point will receive full consideration at the next general meeting.

Still another feature was that respecting local branches. The constitution did not clearly define the organization details, and in view of the announcement of annual dues for the different grades of members, it was thought advisable to have a better understanding on this question, particularly on the point of financing branch societies, before committing themselves. Before the meeting adjourned a short discussion took place on some practical problems, and the interest shown indicated the advantages that would be derived by periodically meeting together and discussing one another's difficulties and experiences. Several present announced their intention of attending the meeting to be held in Toronto on the 26th of this month.

## LLOYD HARRIS LOOKING FOR A SELF-CONTAINED STEEL INDUSTRY

The Editor, Canadian Machinery.

Sir,—My attention has been called to an item in the issue of your journal dated Jan. 13th last quoting from an address I delivered before the Canadian Club at London, Ont. I wish to make a correction which I hope you will publish in your next issue.

When dealing with the Canadian steel industry, I stated that one of the means which we could employ to reduce our imports from the United States is to produce in Canada the $150,000,000 of steel imports we are now bringing in from the United States; that many experts had stated in the past that our steel industries in the interior of Canada would be handicapped for the reason that they had to import coal and ore from the United States as although Canada is rich in iron ores, they could not compete with American ores, on account of their refractory nature.

I went on to say that this situation is likely to be changed, as with the development of scientific methods, Canadian ores are likely to be used in the future. I referred specifically to the fact that the steel industry situated in the eastern part of Canada is exceedingly favorably situated as their coal and ore are at their doors.

I would not like to have the impression get abroad that all the coal used in the Canadian steel industry comes from American mines as I am in hopes that Canada will have a self-contained steel industry in the future by utilizing our own ore resources in all of our steel plants, and that with the deepening of the St. Lawrence River and Welland Canal, we will be able to use Canadian coal in all of the plants in competition with American coal, my thought being that we should make our Canadian industries self-contained to the utmost possible extent.

Yours very truly,
LLOYD HARRIS.

# The Week's Events in Montreal Industry

Thomas Hall, proprietor of the Hall Engineering Works and managing director of the Montreal Drydock and Ship Repairing Company, has been elected as one of the four commissioners for the city of Montreal West.

An address on "The Construction of the Toronto-Hamilton Highway," illustrated by lantern slides and motion pictures, will be given by H S. Van Scoyoc, of the Canada Cement Co., at the regular meeting of the Engineering Institute of Canada, on January 27. The annual general and professional meeting of the institute will be held in Toronto on February 1, 2 and 3.

The Dominion Metal Company, of Sherbrooke, Que., are now distributing to the trade a new line of Olanda products. The Olanda cast steel cement is used for filling defects in steel castings. The Olanda high temperature plastic cement, used for furnace work, will, it is stated, withstand a temperature of 3,000 Fah. Another line is Olanda foundry facing for molding purposes.

C. H. N. Connell, district engineer of the Canadian National Railways, has been promoted to the position of district engineer at Toronto, with jurisdiction over all lines in Ontario. Mr. Connell became associated with the C. N. R. in 1909, when he was appointed engineer of maintenance of way over the Quebec division. In 1914 he was appointed divisional engineer and promoted to district engineer in the early part of 1918.

One of the features of the annual meeting of the Pulp and Paper Association, held last week in Montreal, was the moving pictures shown in connection with present day methods of paper making in its many departments. The films were complete in every detail, showing as they did every essential operation and process, from the planting of the young trees to the making, weighing and rolling of the paper for commercial use, and the transportation of it to the different large centers.

One of the best exhibits of motor cars, trucks and accessories ever shown in the Dominion is now being displayed at the Montreal Motordrome on Sherbrooke. The entire three floors are devoted to the exhibition, and in addition to this it has been necessary to construct an extra building to take care of the overflow. In all about 150 firms are represented at the show including about two score of motor and truck manufacturers. The exhibition will continue all of the present week. Victor Levesque is the general manager.

Walter Lambert, naval architect, 14 Place Royale, Montreal, is now getting prices from Canadian shipbuilders for motor barges for carrying pulpwood and specially designed for shallow draft conditions for mechanical unloading. It is expected, provided prices are acceptable, that contracts for same will be placed immediately, in which case ships will be in service in the St. Lawrence during the coming season, and being of special type will doubtless attract considerable attention. Mr. Lambert hopes at a later date to be in a position to publish plans and specifications of these ships.

Reports of the twenty-first annual meeting of the Canadian Forestry Association, held in Montreal last week, showed that the association had completed one of the most successful years in its history, both as to finances and as to membership, the latter now numbering about 12,500. The forest conservation propaganda carried on by the publicity bureau has been favorably received in all quarters and the good results attained has decided the association in taking further steps to augment these activities that have proven so beneficial during the past year. The president, C. E. E. Ussher, was again elected for the ensuing year, and Robson Black, of Ottawa, was re-elected secretary.

What will be the largest garage in Montreal and one of the largest truck garages in North America is that of the Albion Motors, Ltd., at 63 Prince St. The premises occupied by the Albion is the old central station of the Montreal Light, Heat and Power Company, and the building is one admirably adapted to the use which is now being made of it. The structure extends the whole distance from Prince to Queen streets, occupying 28,000 square feet of floor space and affording over one million cubic feet of shop and storage space. It was opened last May by the Albion Motor Co., and the place has been partly occupied by other interests since then, but with the running out of leases this May it will be entirely occupied by the present owners, the Albion Company having purchased the property.

The Canadian Pacific Railway has announced its intention to offer two free scholarships, covering four years' tuition in architecture, chemistry, civil, mechanical or electrical engineering, at McGill University. The scholarships are open to apprentices and other employees under the age of twenty-one. The necessary requirement will be the passing of the regular entrance matriculation examination provided for in the annual calendar of the University, and the two candidates receiving the highest averages and complying with the requirements for admission will be awarded the scholarship and have the option of taking any of the above courses. Rules governing the continuance of the course provide that the holder shall meet the necessary requirements for the next higher year. Interruption to studies may be granted by giving due notice to the railway company.

## LOOKING FOR A RECORD YEAR NOW

**Dealer in Contractors' Equipment Has More Inquiries Than Ever This Season**

Canadian Machinery had the opportunity this week of discussing trade prospects with the representative of a firm specializing in new and used contractors' equipment. There was no doubt in the mind of this dealer regarding the business they were likely to do this year, and he was ready to brand it as likely to be "the best year's business we have ever done."

"I am basing this statement on the number of inquiries that are coming in now regarding the securing of equipment for the 1921 building season, and a number of these want to get delivery very soon in order to be in shape to put in a full season's work. Nor can it be said that these inquiries come from any particular section, as nearly every corner of the country is represented in the list."

## U. S. RECOGNIZE BRITISH EXPERT

**Sir Robert Hadfield Brought Out Steel of Great Use During War**

Sir Robert Hadfield, inventor of manganese steel and leader of the British steel industry, has been awarded the John Fritz gold medal for notable scientific and industrial achievement, it was announced by the John Fritz Medal Board, of New York, representing five leading United States engineering societies. Manganese steel was first described by Sir Robert in 1893, but it did not become generally known until the war demanded armaments in which toughness was combined with great strength. Manganese steel is non-magnetic, and millions of helmets made of this material were worn during the war by British, United States and Belgian soldiers. In addition to inventing manganese steel, Sir Robert discovered magnetic steel of high permeability especially suited for use in dynamos and motors.

# RICH
## TWIST DRILLS

THE BLANK

THE FINISHED DRILL, RICH STANDARD №20

RICH HIGH-SPEED DRILLS are not brazed, welded or built up, but forged from the bar and twisted at the proper temperature, giving them physical properties superior to those of the original bar. They are built to stand hard duty and retain a keen edge for long periods.

Other RICH products consist of TRACK and BOND BITS, BRIDGE REAMERS, RIVET SETS and COUNTERSINKS in a wide range of sizes and styles, all distinguished for the quality and quantity of work which they perform.

# THERE IS AN OPENING IN THE BRITISH MARKET FOR CANADA

MR. CECIL G. HORTON, assistant manager, Engineering and Machine Works of Canada, St. Catharines, has spent some time in Britain introducing a new type of steam shovel. Some of his observations should be useful to Canadian exporters:

"When one is situated as we were with a product to introduce which was comparatively unknown in Great Britain, I only know of one sound plan of action. You must go over and study the market for yourself. When you get there you should spend considerable time in gathering up all the information available bearing upon the successful introduction of your product. Then you should spend a little longer in sifting out that information before acting. It is best to make sure of your ground before the buyers even realize that you are in the country. The ordinary channels of publicity will not serve you at first and it will be futile to attempt any general appeal to the buyers. No unknown machinery will be taken up by the British market until its value has been demonstrated to the individual purchasers, and you should not begin to look for sales until you have digested the salient features and the peculiar tendencies of the market which you are attempting.

"When your preparations are complete and you are ready to approach prospective customers, your attitude and method are of first importance. Today Canada enjoys distinct prestige in Great Britain. More than that, Great Britain is beginning to realize that Canada can manufacture. So that the way you go about your business is of utmost importance, as you are creating impressions of Canadian selling methods that will last far beyond the present instance. Moreover, it is wise to distinguish Canada from North America. There is no better way to impress this fact on the British buyer than by observing a studied caution and moderation in salesmanship. The first great fundamental for all salesmen in the British market is to watch their language. The British dislike exaggeration in any form, and they expect you to be explicit and straightforward in all your dealings with them. You must have conclusive proofs regarding your product, and you must convince them with a minimum of superlatives. They are suspicious of too much virtue, and are not inclined to take what Americans and Canadians would consider justifiable chances. I do not mean that they are not receptive and open to conviction; but I do think that greater care is necessary to ensure successful business in Great Britain than in our own market. Now, a salesman perhaps cannot change his methods overnight, but if he studies British business men, he can quickly ascertain their etiquette and their prejudices; and this must be the first achievement of the successful Canadian exporter.

"As we were introducing an article hitherto unused, our main approach to British buyers was direct, and advertising was a secondary consideration. However, I believe that the British trades papers could be used successfully when once an article has been introduced. They are widely read, and are excellent, especially in a technical sense. Exhibitions also play a considerable part in advertising and sales campaigns over there. These exhibitions are planned without reference to any sight-seeing, and they attract the most aggressive elements of British business. As to general advertising, there should be co-operation between the Canadian manufacturer and his British representatives. The manufacturer at home is in a position to compile advertising information, and the representative abroad can effectively handle the distribution. Personally, we found the Trade Commissioner service of value in putting us in touch with the buyers, and believe that this service could be used more by Canadian manufacturers for the securing of both information and connections.

"For representatives, we found it expedient to use the established British importing houses. Here again the fact that we were introducing a hitherto unused article governed our choice. These importing houses have very wide connections, and they give immediate access to trade circles. It seems improbable that anything resembling an export pool could be successfully formed by machinery manufacturers. Machinery products are intricate as a rule, and the more direct the route from the manufacturer to the user the better. The question of foreign representation arises in other than the sales capacity in machinery lines. The matter of a service station abroad must be considered, as the best of mechanics cannot master a new machine overnight. At present we ship k.d.s. (knocked down state), and our mechanics assemble our machines abroad. With increased sales this may or may not necessitate permanent technical representation abroad, but it is a point to be considered when one is entering the export field.

"In conclusion I would like to emphasize the opportunities for Canadian machinery. Great Britain needs more houses than she can possibly construct. I visited one center near London where a complete new city was being built with authorized plans for a population of sixty thousand. There are other developments of almost equal magnitude, so that it would be difficult to exaggerate the openings for every sort of building material. Speaking more particularly for firms similarly placed to ourselves, it would seem wise for Canadian manufacturers to exploit their present-day advantages, because, although money is tight now and the rate of exchange unfavorable to the British buyer, as these two factors approach normality competition will become keener and established connections will then have value all their own. With British buyers such a connection is well-nigh permanent if only the seller watches his end properly."

## Trade Gossip

**Build Coke Plant?**—The Semet-Solvay Co., the largest concern of its kind in the world, is considering building a four million dollar by-product coke oven plant at Hamilton, it is announced. It is said this would produce all the artificial gas necessary to meet Hamilton's needs for several years.

**Have Orders.**—As the result of the annual furniture exhibition at Kitchener the furniture industries there have been provided with large orders by buyers from all parts of Canada and some of the leading cities of the United States. Manufacturers here express entire satisfaction with the outcome of the exhibition and claim that there are bright indications of early revival of the furniture trade.

**In the Maritimes.**—Hon. E. K. Spinney, minister without portfolio, has arrived in Ottawa from his home at Yarmouth, N.S. Mr. Spinney expects to remain here until after the opening of the session. Mr. Spinney stated that there was little unemployment in the Maritime provinces outside of St. John and Halifax, and that business conditions were as good as could be expected during the present period of readjustment.

**Conditions in West.**—A Winnipeg report says:—G. E. Carpenter, secretary of the prairie division of the Canadian Manufacturers' Association, who attended the manufacturers' conventions in Edmonton, Calgary and Medicine Hat, reported that great confidence was expressed at these gatherings regarding market conditions for 1921. Every effort is being made, Mr. Carpenter reported, to keep plants running at full strength. In respect to unemployment in the west, such distress as prevails is being efficiently handled, Mr. Carpenter said. In his opinion, lack of employment was not as severe as in many former years.

**Showed the Books.** — The Dominion Steel Corporation opened its books to a committee of its employees which waited on the management so that they could see for themselves that orders are slack and the recently announced wage reduction necessary. The committee called to ask General Manager Merrill to cancel or at least modify the 20 per cent wage cut. Concerted efforts to end the strike of railway yardmen at the Dominion Steel Corporation plant and the Nova Scotia Steel and Coal Company's plant are being made by the steel companies, the federal department of labor and the Canadian National Railways, it is claimed in the Brotherhood of Railway Employees circles.

BERTRAMS LIMITED
SCIENNES EDINBURGH

W. F. Pollock, president Victor Saw orks, Springfield, Mass., was at the amilton, Ont., office for several days st week.

H. W. Holmes has accepted a position th the Canadian Hart Products, Ltd., sales manager. Mr. Holmes was for veral years manager of the Hamilton, t., plant of the Victor Saw Works.

The Canadian Ingersoll-Rand Comny, Sherbrooke, Que., has secured the nadian rights for manufacturing Telith crushers and primary breakers as ilt by Smith Engineering Works, Milukee, Wis.

Wiggett Electric Company, 82 Welgton Street, Sherbrooke, Que., forerly Electric Motor and Repair Comny, will move into their new building above address shortly and will do all rts of motor repairing and selling of otors up to 50 h.p.

The Dominion Government has awardthe Sheehy Bros., of Peterboro, the ntract for the construction of a new m across the Otonabee River at Nasu, a short distance from Peterboro. e dam will, it is estimated, cost about quarter of a million dollars, and is to completed by December, 1922.

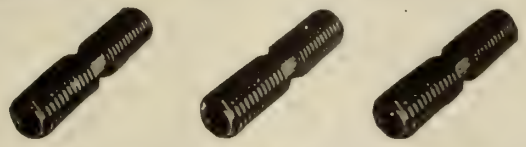
Mrs. Clara E. Speight-Humberston, 62 orold Avenue, Toronto, claims she has complished the transmuting of zinc o copper by means of electric curnts, using a solution of granite. If s has been actually achieved, it will mpletely revolutionize our knowledge transmutation of metals.

The death occurred on January 20 Major Alfred T. Tomlinson, a pronent civil engineer, at his home on enue Road, Toronto, following an illss of two months. Major Tomlinson s a member of the Engineering Intute of Canada, the American Society Civil Engineers and the American gineering Association.

The steel makers along the northst coast of England have adopted a licy of drastic price cutting, said to owing to the increased foreign comtition, which has virtually stopped deands for the dear home made articles. e reduction ranges from £2 per ton rails and ship plates to £4 for billets.

The Lang Manufacturing Company, e of Guelph's infant industries, has rged ahead rapidly since its establishnt in May, 1918. Since that time the all building in which it began its reer has been enlarged twice to accommodate the increasing business. The Lang company first manufactured Guelph convertible seats, but soon nched out into the manufacturing of chitectural iron work, flax machinery, dium and small rubber moulds, welded tanks, special small machinery, and a general machine business. They also do a big business in oxy-acetylene welding.

Evidence of its growth is shown by the fact that at its beginning two men, members of the firm and skilled mechanics, did the work and the employees now number 23. One of the most important products lately placed on the market and which is attracting much attention is a bearing of unusual design. It was invented by William Ridsdale, of Guelph, and is called the Ridsdale reinforced bearing. The idea is this: A spring or spiral made of a certain alloy is placed in the bearing cap or housing. Babbitt is next poured into the bearing, but the babbitt is merely a holder of the reinforcements. The claim for this bearing is that there are no hard spots in such construction, also that the cheapest grade of babbitt can be used with good results as the wear comes on the reinforcement and not on the babbitt. The company claims that it can be used in any bearing including those where speed and pressure is extreme. The bearing is said to have a tensile strength of 36,000 pounds per square inch against a much lower figure for babbitt only.



The firm is popular with its employees, no doubt to some degree due to the splendid working conditions provided.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

All Screws Are Reversible

SCREWS are made of the best grade steel. Both ends are broached and are heat treated after machining. They are reversible, so that either end may be used, are large enough in diameter to stand the torsional strains applied by operator when setting up his work. They are made to give the best service—and may be depended upon to stand up under the hardest usage.

BRANTFORD, CANADA

Fatal Accident.—Lying on his stomach, looking down an elevator shaft in the Sunbeam Lamp Works, 221 Dufferin street, Toronto, George J. Pond, aged 45, of 15 St. Clarens avenue, was crushed to death by the elevator cage. Fred Read, 146 Booth Avenue, was searching at the foot of the shaft with a lantern for a gold locket which had been dropped. He was standing in the pit below the basement and the elevator does not descent below the level of the basement. This saved Read from meeting with the same fate as Pond. The machinery of the elevator was started through some unknown agency, and the cage slid down the shaft pinning Pond and crushing his skull. The body was removed to the Morgue, and an inquest will be held. Mr. Pond is survived by a widow and six children.

Orders are short.—It was stated by an official of the Dominion Steel Corporation, Sydney, N.S., that unless new business was booked, the plant would suspend operations next week. To the present the plant has been working on outstanding orders, but no new ones have been received, and the outlook was none too good. Unless these are received or unless the head office in Montreal orders the manufacture of stock to be kept on hand until called for, prospects were for a shutdown at least temporarily next week.

### MACHINE TOOLS—BORING MILLS

1 - 60" Bullard Boring Mill. Used, but in good condition
1 - 61" Bullard Maximill, with two swivel heads and plain parallel slot table with one set of four XAP-2 Independent Face Plate Jaws with Steel Bodies with Type G Motor Bracket without motor. Used only a short time.
1 - 60" Colburn Vertical Boring Mill. Used, but in as good condition as when new.
1 - 36" Bullard Vertical Turret Lathe, New Era Type, equipped with three-jaw combination chuck, built into table with type F motor bracket, with cutting lubricant system and four KT3 tool holders, complete without motor. New, never used.

### LATHES

1 - 18" x 8' American Lathe, back guard, complete with countershaft. Used, but in good working condition.
1 - 15¼" x 6' Jameson Lathe, double back geared, complete with countershaft. Used, but in good condition.
1 - 18" x 8' Walcott Lathe, with taper attachment and countershaft complete.

### MILLING MACHINES

1 - No. 4 Cincinnati Milling Machine, complete with standard equipment. New, never used.

### DRILL

1 - 48" Scott Heavy Duty Radial Drill, complete with standard equipment. Used, but in good working condition.

### SAWS

1 - No. 26 Higley Cold Metal Saw. Takes blades 33" diameter x 3/16" to ⅜" thick. Table 3' x 7' 3½". Height of table 27". Pulley 16" x 4". Practically new machine.
1—Espen Lucas Cold Saw. Used, but in fair condition.

### RUBBER MACHINERY

2 - 60" Mills. New.
4 - 60" x 12' Horizontal Heaters. New.
4 - 48" William's Vertical Heaters. New.
1 - 100 Gal. Day Mixer. New.
1—60" Spadone Bias Cutter.
1 - 66" Birmingham Calendar with Falk Gear Unit and Motor complete. New.
2 - 500 Gal. Cement Storage Tanks with Agitator, complete.

### REGULATORS

1 - Mason Regulator, 2", 100 lbs. to 40 lbs. New.
4—Mason Regulators, 2", 100 lbs. to 60 lbs. New
4—Mason Regulators, 1", Type C.C., 100 lbs. to 20 lbs. New.
4—Crane Regulators, No. 962, 1"
25—Crane Regulators, No. 962, 2".

### THERMOMETERS

20—New Bristol Recording Thermometers, Model 240, Bulb 252, each with 25' of bronze armoured connecting tube and chart No. 664. Complete in moisture-proof cases.
20—New Tagliabue Straight Stem Thermometers, 200 to 350 deg.
5—New Tagliabue Angle Stem Thermometers, 200 to 350 deg.
5—New Tycos Straight Stem Thermometers.
4—New Tycos Thermometers, No. 28, 9" Scale. Range 0 to 200C.
8—New Tagliabue combined Fahrenheit and pound steam pressure, 100 to 250 deg.

### TRAPS

10—No. 4, Model "D" Anderson Steam Traps. Used, but gone over and are in perfect working condition
4—½" No. 11 J. M. Steam Traps.
1 - ¾" No. 2 J. M. Steam Trap.
1 - 1" No. 3 J. M. Steam Trap.
1 - 1½" No. 5 J. M. Steam Trap

### SCALES

1 - National Weighing and Counting Scale. Platform 24" square. 600 lbs. capacity, with counting scoops.
1—New Brantford Blue Dial Scale. No. 20 capacity 20 lbs. in tenths

### TANKS

1—Steel Plate Storage Tank, 60" diameter, 25' long, 3,000 gals. capacity, 3/16" plate in shell, ¼" in head, manhole in middle of shell, 2" outlet on each side of manhole.
1—Only 50 gal. Bowser Tank with pump and agitator, mounted on large rubber-tired wheels. New, never used.

Address any enquiries you wish to make regarding these items to: "By Products Dept., The Goodyear Tire & Rubber Co. of Canada, Ltd., New Toronto, Ont." Full details and prices gladly furnished on request.

If you are in the market for any equipment or supplies which does not appear on this list, let us have your enquiry about it. Possibly it has been turned over to us since this bulletin was issued.

***Write for list of Engineering and Factory Supplies we have to offer.***

### REELS

100 Heavy Steel Reels. Diameter of Flanges 30", diameter of drum 10", between flanges 20", bore 2" weight 130 lbs

### STEEL

2,000 lbs 1¾" Square Machinery
1,000 lbs. 1½" Round Machinery
1,100 lbs 1¾" Round Machinery
4,000 lbs 1¾ x 2" Machinery.
100 lbs 2⅜" Hexagon C.R.
225 lbs. 1⅞" Hexagon C.R.
1,561 lbs. ¾" x 4" Oil Hardening Carbon Steel "Ketos"
326 lbs. 1" x 4" "Ketos" Tool Steel.
485 lbs. 1" x 5" "Ketos" Tool Steel.
237 lbs 1¾" Square Full-speed Steel.
258 lbs. 1¼" Square Carbon Steel.
127 lbs 1" Rd. Carbon Tool Steel.
138 lbs. 1¼" Hex. Cast Steel.

REG. TRADE MARK
TRAHERN
REG. U.S. PAT. OFF.

Circulating Pumps are suitable for use on Machine Tools of all kinds.

They are Rotary Geared. They deliver heavy streams of water, oil, or compound without pulsation; will reverse automatically with machines; operate against 100 lbs. pressure and supply copious streams of coolant. They run at low speed, minimizing upkeep and giving longer life to pumps. When properly installed they will not lose prime.

**Our Bulletin 44 explains in detail.**

# Let them know it's there

In complimenting us upon the results secured from their advertisement in this section, one advertiser said:

> "Of course we would not have sold it without letting people know it was here, that is obvious, and thanks are due you for letting the people know it was for sale."

If you have any old or used equipment for sale, let people know it's there. Your message in Canadian Machinery will be placed before the probable buyers of such equipment.

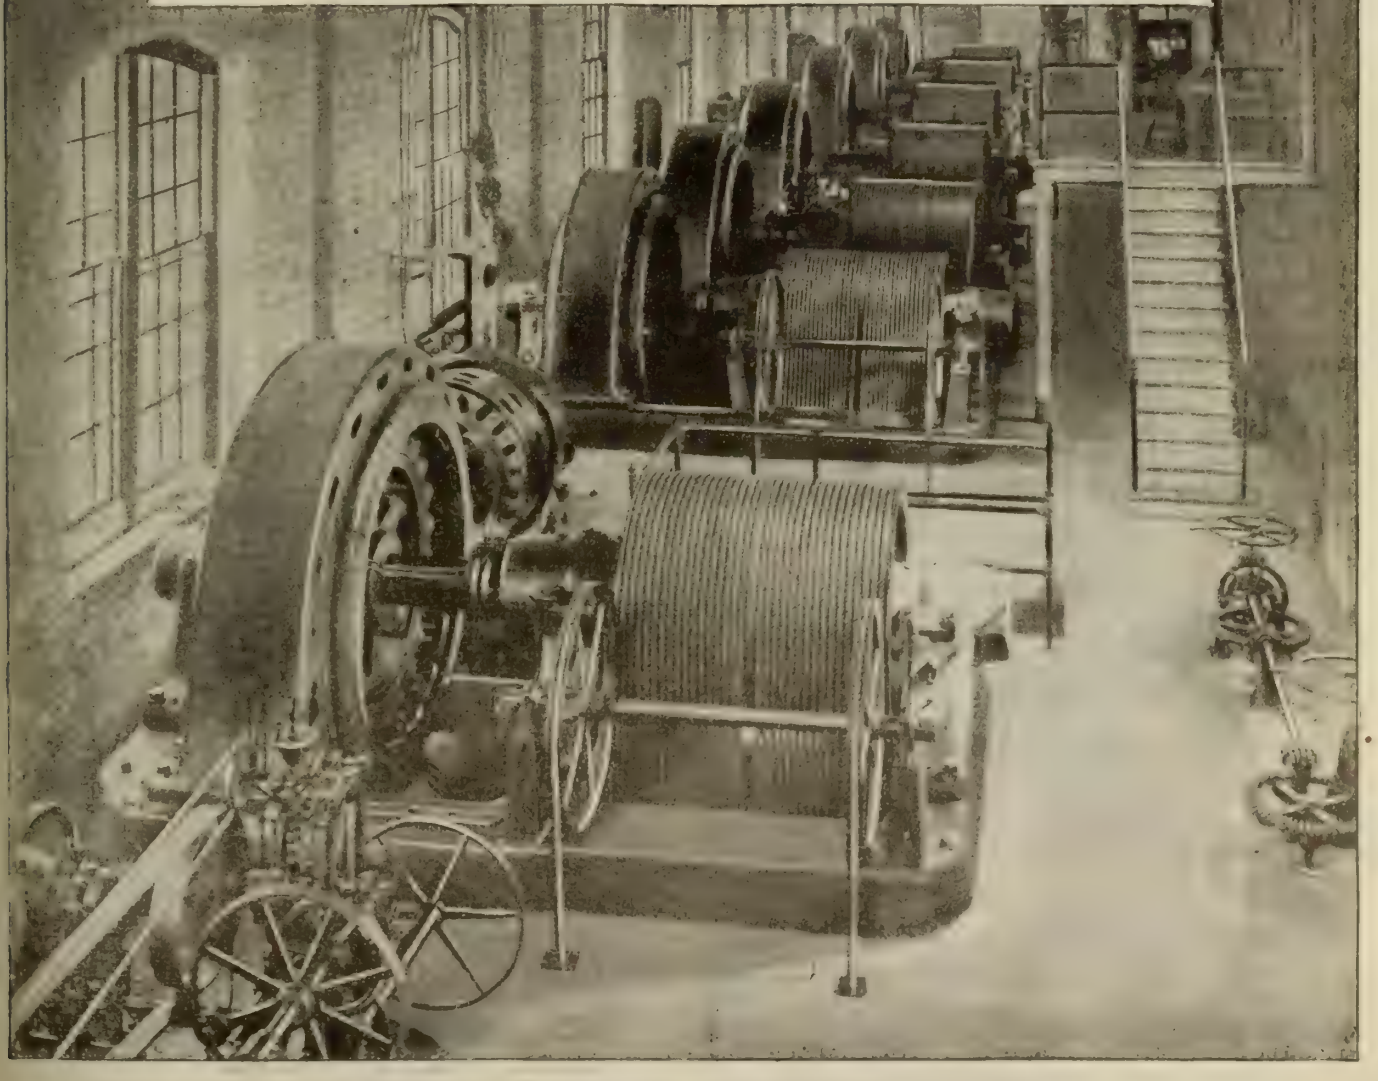
# "Built by Dodge"

Seven generators connected by Dodge Rope drives direct to the turbine shafts; this was the way "Dodge" solved the problem for one light and power company.

If you were to read a list of central stations using power harness "built by Dodge" you would see represented many of the most important ones in America.



"Built by Dodge" has meant entire installations weighting millions of pounds and costing thousands of dollars; again that mark of superiority attaches itself to a single pulley, a clutch, a hanger, a bearing, a coupling or a collar; equal quality, equal value applying in either case. Everything for the mechanical transmission of power is "built by Dodge"; each product carrying the basic thought, conservation of energy.

Laying the roadbed for power with Dodge equipment immediately provides for the efficient and wasteless transporation of energy from where it is created to where it is needed.

When Dodge quality is known, it is usually specified by both buyer and seller of transmission equipment, because the owner of a Dodge installation is always ready to admit triple value for his money in quality of product, correctness of engineering suggestion and interchangeability of units from one use to another.

Heavy Duty Draw Cut Shapers, Special Heavy Duty Draw Cut R.R. Shapers, Special Locomotive Cylinder Planers, Traveling Head Planers, Special Roll Wobble Planers, Portable Planers, Stationary and Portable Keyway Cutters, Finished Machine Keys. See our full page advertisement in the first issue each month of "Canadian Machinery."

# OILGAS
INDUSTRIAL FURNACES
Most modern, efficient and economical heating method. Made in Canada! Full details on request.
General Combustion Co. of Canada, Limited
619-623 New Birks Building, Montreal

# Greaves-Etchells Electric Furnace
FURNACES FOR EVERY PURPOSE
Electric Furnace Construction Co.
908 Chestnut Street Phila., Pa.

# Toronto Testing Laboratory LIMITED
METALLURGISTS CHEMISTS FUEL ENGINEERS
160 Bay St., Toronto.
Tests of Metals, Fuels, Oils, Water, Etc.
INDUSTRIAL RESEARCH

PAGES

Are for You

THE TUBE COMPANY OF CANADA LIMITED
# Steel Tubing
for all purposes
*Electric and Oxy-Acetylene Welded*
*Also*
*Butt Seam Tubing*
Hot or cold rolled, in sizes ⅜ to 2 inches outside diameter, from 16 to 22-gauge. Also equipped for bending 16-gauge or lighter, any shape or radius. We furnish any shape — Rounds, Squares, Hexagons, Ovals and Special Shapes to customers' specifications.
**Expert advice given on all Steel Tubing Problems.**
The Tube Company of Canada
233 Dufferin St. TORONTO, ONT.

# Oil Tempered Steel Springs
—for every purpose and the best for each use.
Special styles of all kinds to Order.
THE CLEVELAND WIRE SPRING COMPANY
Cleveland, Ohio
U.S.A.

THE
NATIONAL AUTOMATIC TOOL CO.
Richmond, Indiana, U.S.A.

*If what you need is not advertised, consult our Buyers' Directory and write advertisers listed under proper heading.*

# Canadian Machinery BUYERS DIRECTORY

**If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index—last page of book, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.**

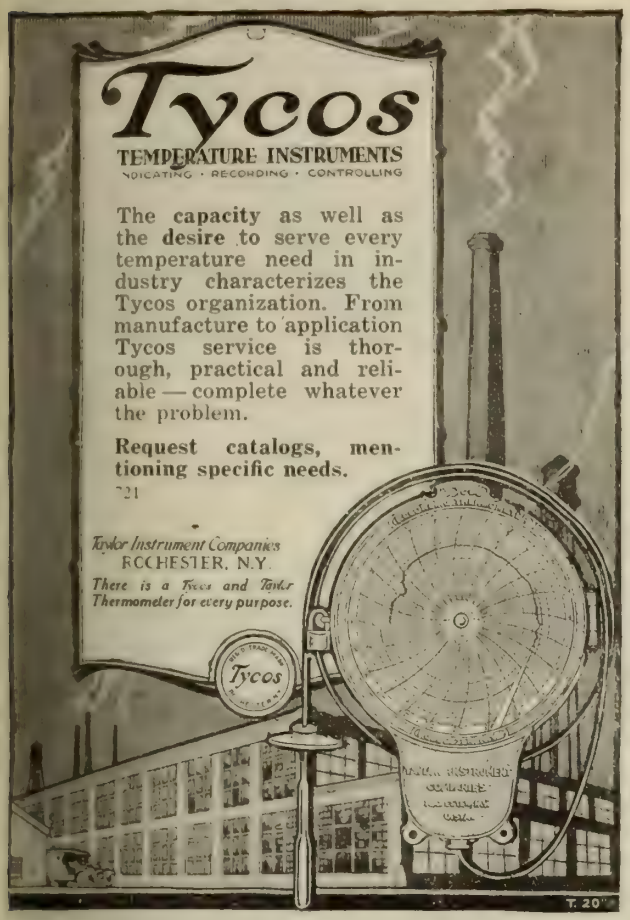
# Would You Like to make some Extra Money?



Of course you would. Well then, why not do so? Canadian Machinery is always on the lookout for well-worth-while ideas, and are willing to pay a good price for them.

We are often asked, "What sort of ideas do you want?" Briefly, what we are desirous of obtaining is this, "Any idea that has proved of value in the machine shop, drafting room, or tool room." Think of how you got over some difficulty, a ticklish piece to hold in the lathe, or perhaps how you increased production on some particular piece. Any idea that saves time or money in the machine industry will appeal to us. Never mind the style. Write it as best you know how. We will put the finishing touches to both the wording and the sketch. Start in **NOW** and send us something of such a nature.

*Address it to*

**The Editor, Canadian Machinery**

# HENDEY LATHES

Installed in the plant of The Davenport Machine and Tool Company Rochester, N.Y.

# An Accurate Production Job

A PRODUCTION job requiring great accuracy is a **real** test for a lathe. Here is one which proves the merit of the Hendey.

It is a small plate face job—machining a Davenport inner spindle into which the chuck is screwed. The operations consist of recessing, threading, turning and boring. Nine hours only are allowed for twenty-five fully finished pieces.

Several years ago the Davenport Machine Tool Co. of Rochester, N.Y., purchased two Hendey Lathes for this work. Such satisfactory service did these machines give, that, when two additional lathes were required, Hendeys were chosen. Their tool room, showing the four Hendeys, is illustrated above.

# "SANDUSKY" STOCKS AND DIES

*THE BEST PIPE THREADING TOOL*

No. 1 PLAIN "SANDUSKY" STOCK AND DIES.
Threads 1", 1¼", 1½" and 2" Pipe.

The "SANDUSKY" Stock and Die is made only of the very best materials. Dies and Cone Rings are made of superior steel, and other vital parts of a high grade malleable iron. It is the best and simplest pipe threading device made.

It has the exclusive advantage of the "Automatic Throw-out of the Die," "Taper Cone Ring," and the "Guided and Supported Leader Screw," three features patented by us and which can only be found in the "SANDUSKY" Shells and Dies.

You will note from illustrations that the "SANDUSKY" Stocks and Dies have very many less parts than others, and are unqualified, and most durable pipe threading tools of any type.

These tools are all finished in green enamel, insuring an attractive and durable finish, another exclusive feature.

They are packed each complete with dies, one in a box.

Note: All stocks furnished with either Whitworth or U.S. Standard dies. Please specify kind of thread required on order.

"SANDUSKY"
No. 1A RATCHET STOCK AND DIES
Threads 1", 1¼", 1½" and 2" Pipe.

"SANDUSKY"
No. 2 GEARED STOCK AND DIES
Threads 2½", 3", 3½" and 4" Pipe.

# You Need a Good Die Stock Set

if you need one at all.

Because a **GOOD** Die Stock Set embodies:

1. Accuracy in its product.
2. Adjustment for wear.
3. Free cutting qualities.
4. Provision for sharpening.
5. Ample adjustment for oversize or undersize.

**P. & W.** Die Stock Dies **ARE GOOD DIES.**

**BETTER** than most because of the interchangeable feature in their chasers. A broken chaser in a P. & W. Die doesn't mean a new set of chasers. You can get a new chaser to replace a breakage and the new one "fits in" perfectly in your old set. That's the 6th point, **"ECONOMY IN OPERATION."**

# *The* "Clipper" Solves Difficult Lacing Problems

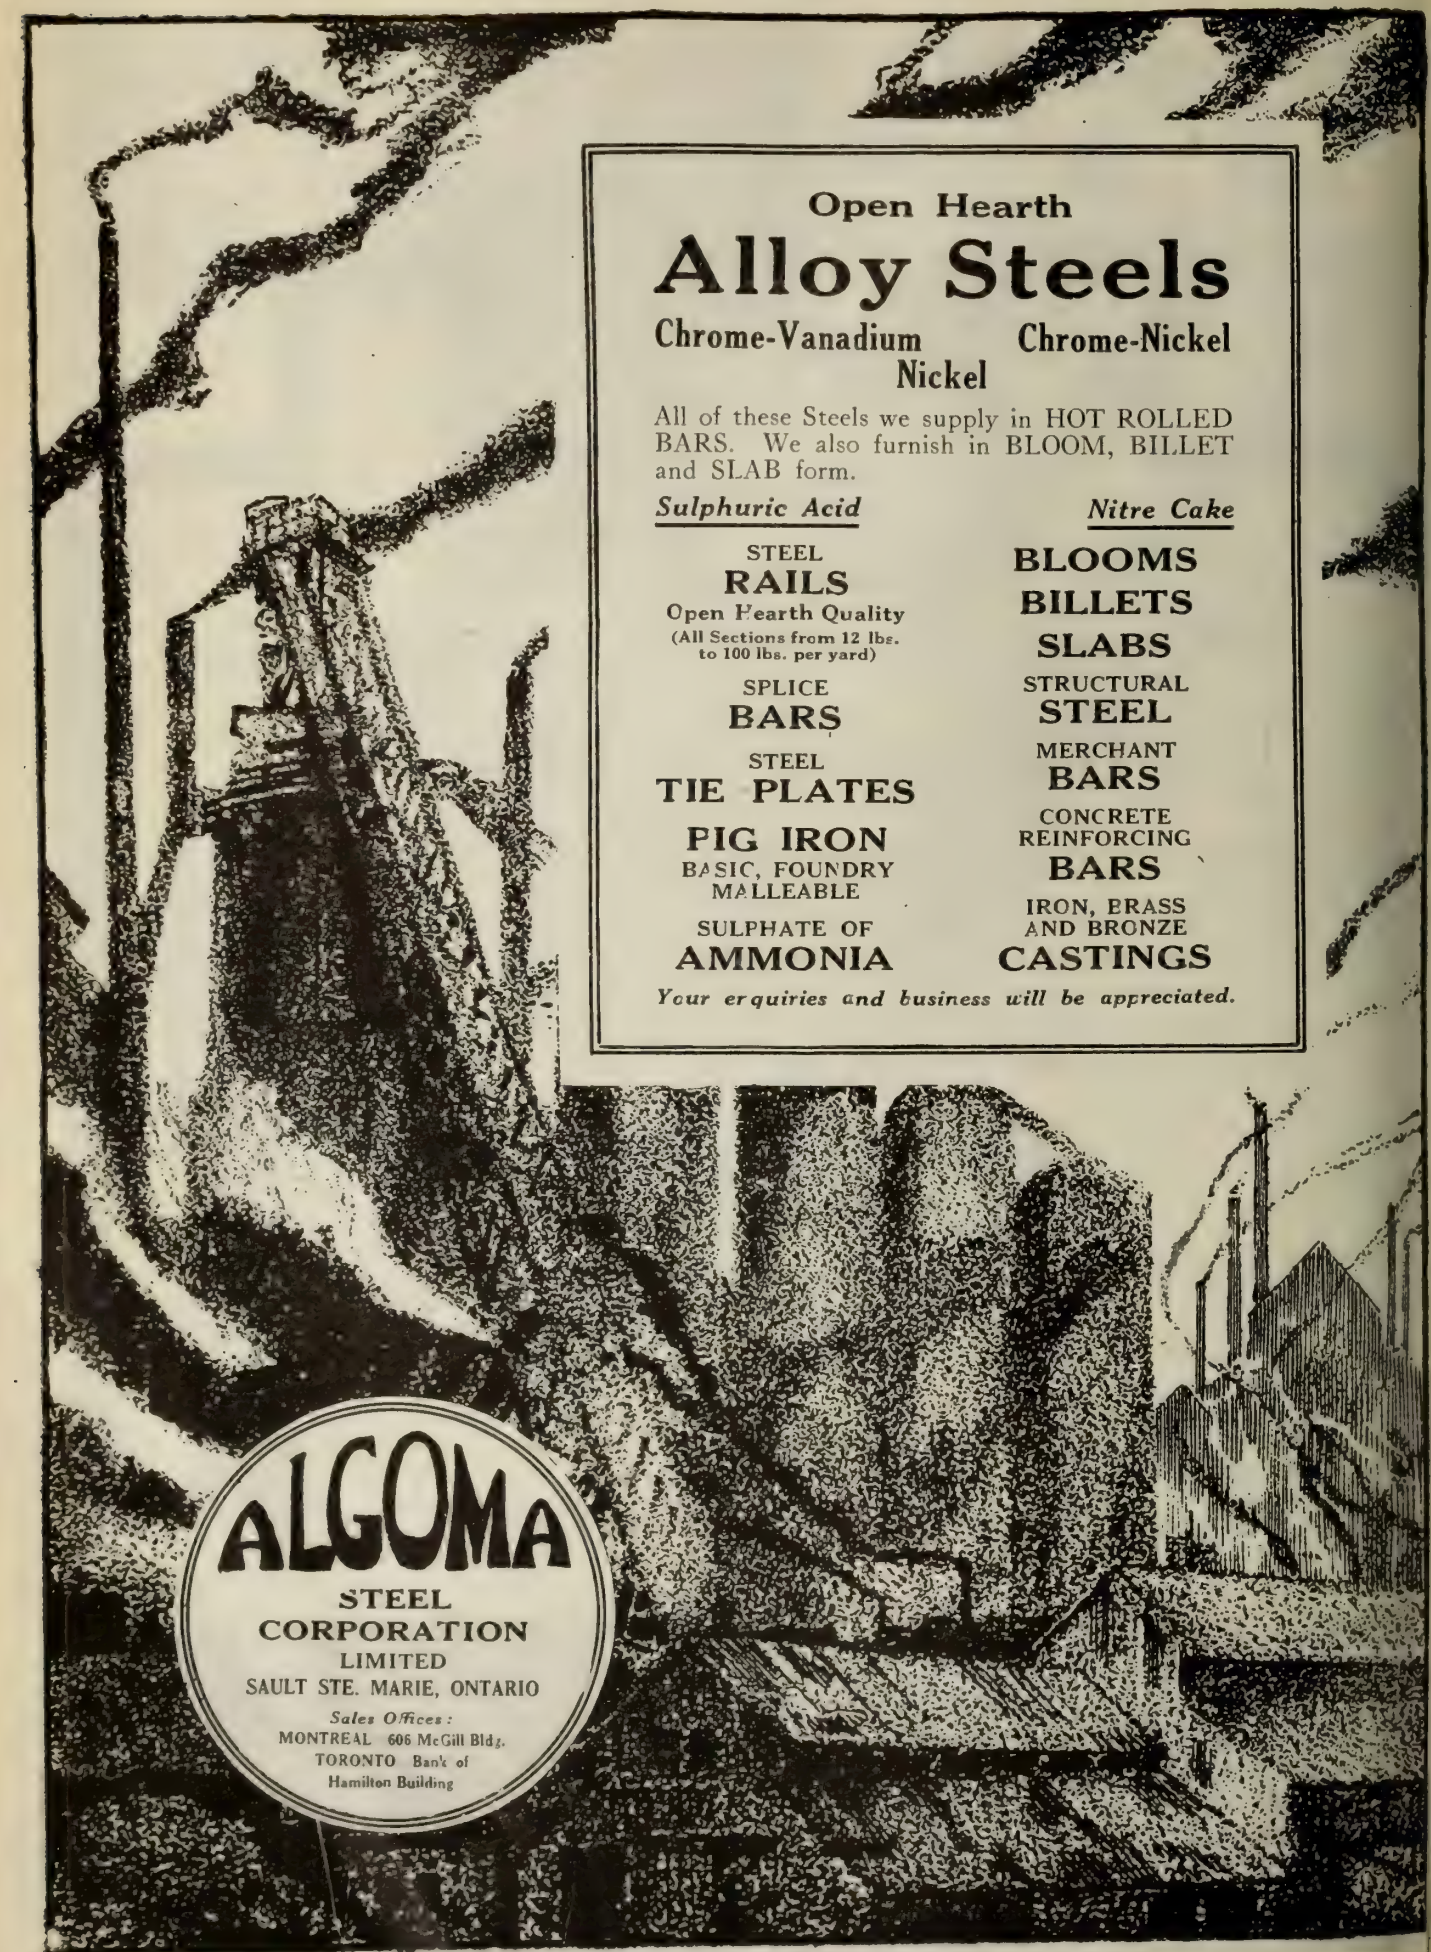
THE difficulties encountered in using *quarter-turn drives* can be overcome by installing an idler *set at the proper angle* to direct the line of belt travel as shown above.

Before the installation of the idler this was a plain quarter-turn drive. The machine was a veritable "Belt Eater." No endless or laced belt could stand the strain. Belt expense was excessive.

By the use of an idler much greater pulley contact was obtained, horse-power was increased materially and all injurious side-strain eliminated. Since with an idler both sides of belt come in pulley contact, it was necessary to use a laced joint *smooth on both sides*. "Clipper"-laced Belts are now lasting as long as on straight drives.

## The Clipper Belt Lacer
## Laces a Belt in Three Minutes

It makes the smoothest possible joint, with a perfect hinge action that hugs the pulley and runs true. The "Clipper" Belt Lacer is so simple that any workman can successfully lace a belt with it. It is backed by a perpetual guarantee and goes to responsible parties for free trial.



*Most mill supply houses sell the "Clipper."*
*Dealers not stocking it write for particulars.*

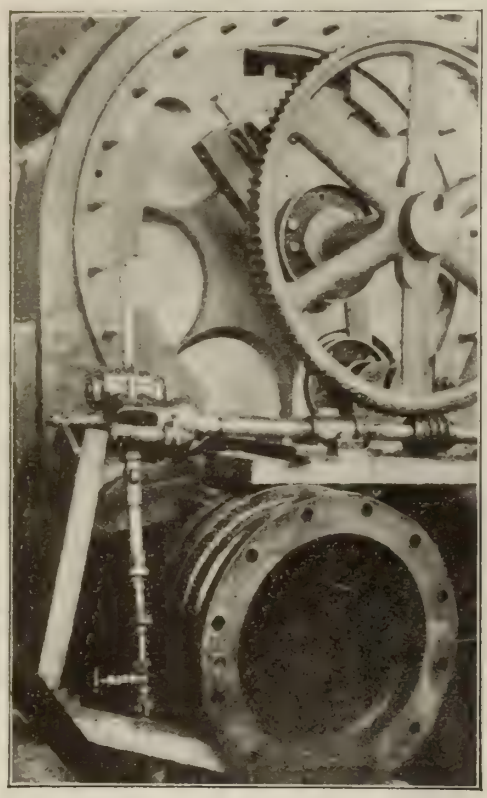
MORTON

# Increased Driving Box Repairs Forced the Purchase of this Morton Draw Cut Shaper

Delays to output were traced direct to driving box repairs in this busy shop. Time element and shortage of man power were considered and the installation of this "Morton" reflects the good judgment of these thoughtful officials to install machines of guaranteed production power.



This Morton handles all the machine work on driving boxes—planing to thickness, planing shoe and wedge faces and crowning for bearing brass. It simplifies handling and reduces machine time.

May we send Bulletin A-6 explaining numerous points of merit?

**MORTON MFG. CO.**

**Muskegon Heights - Michigan**

# Weighs 40 Pounds
## *Lifts 4 Tons*

This cut illustrates a No. 2 Little David Drill reboring a 40-inch air compressor cylinder at a large Ontario mine.

Speaking of the power of this drill, the master mechanic said: "The cylinder weighed in the neighborhood of four tons, and at times, if the boring tool stuck, the Little David Drill would lift the entire casting enough to be noticeable."

You do not buy pneumatic drills on the basis of their hoisting ability, but when the question of adding to your tool equipment comes up and you choose a Little David, it's interesting to know that the tool of your choice has the power and the stamina to stand up under such an overload as this.

Shops all over the country find Little Davids rugged, highly efficient, easy to operate, and readily portable. Ask for a set of Little David bulletins. You'll find them of interest.

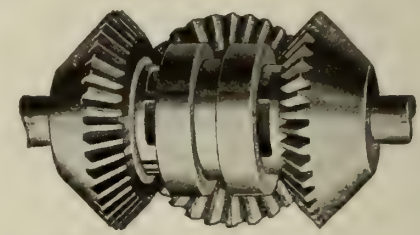
# THE JOHNSON FRICTION CLUTCH

## Clutches for Reversing Functions



Johnson Clutch Installation on a Newton Milling Machine

A reversing clutch is a very common requirement on machinery, and one which is encountered in many different forms. Whatever the situation may be, a Johnson Clutch offers the best method of handling it.

The bevel gear assembly shown here is one of the ways in which a Johnson Double Clutch is frequently applied for reversing functions. Many of the best machine tools are equipped in this manner.

MAGNOLIA ANTIFRICTION METAL

TRADE MARK

*New Truths and Old Fallacies*

# Hardness of Alloys—*Continued*

The differences in the measurements of the sustaining powers, under pressure, between tin-base copper hardened metals, and lead base metals, free of copper, as shown by tests by the American Society for Testing Materials, is so slight that in some cases it is not more than the breadth of a hair.

In a test, made for us some years ago, Magnolia withstood 19 per cent. greater stress than a Genuine. This test loses some value because we do not know the brand or formula of the Genuine.

In 1912, Professor Robert H. Smith, an eminent mechanical engineer and authority, tested Magnolia against an imitation. In this case Magnolia withstood 16,980 pounds (7½ long tons) per square inch pressure before the test block collapsed. When it is considered that this was a small cylindrical shaped test block, unsupported on the sides to prevent spreading, it is evident how much heavier a strain Magnolia will bear without distortion, when supported in recesses of a shell, and what a large factor of safety it provides.

For copy of complete article:

***"New Truths and Old Fallacies"***

Address our Montreal Office

Professor John Goodman, an equally eminent mechanical engineer and authority, says of Magnolia: "My experience distinctly shows that the higher the pressure applied to a Magnolia Bearing, the better does the wearing surface become." He also says: "I ran a Magnolia bearing for some weeks under a pressure of two tons per square inch, at a surface velocity of 250 feet per minute; the temperature maintained at 130° Fahrenheit, by circulating water through the center of shaft. After the run the surface was perfect, although the lubrication had been meager, viz: 0.002 lbs. of oil on a pad weighing 0.002 lbs."

(Continued next month)

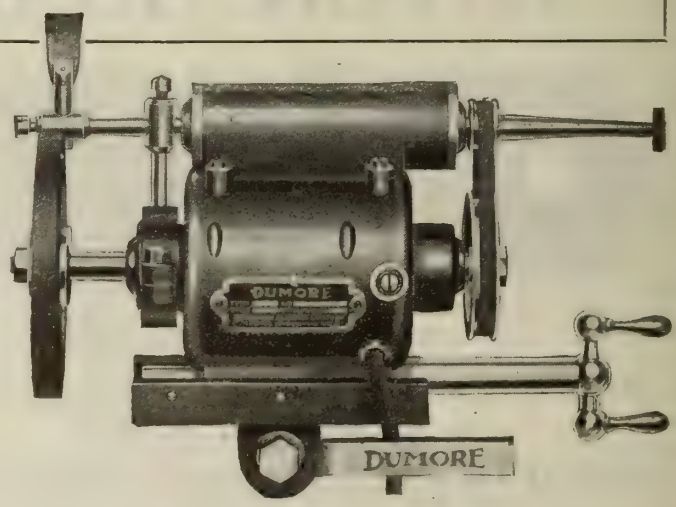
## A Good Example of What Can Be Done With



# DIE-CASTINGS

The popular grinding machine herewith illustrated is a good example of what can be accomplished by the Die-Casting process. The parts of this machine are die-cast, which represents a big saving in time and expense over any other method of construction.

The Die-Cast parts used in this grinder required no machining. They were delivered in perfect condition, ready to assemble. This is the big feature of all die-cast parts. They are accurate, and smooth in finish.

Die-Cast parts can be profitably used for many purposes. Send us your blue prints or samples for estimates.

**Largest makers of Die-Castings in Canada.**

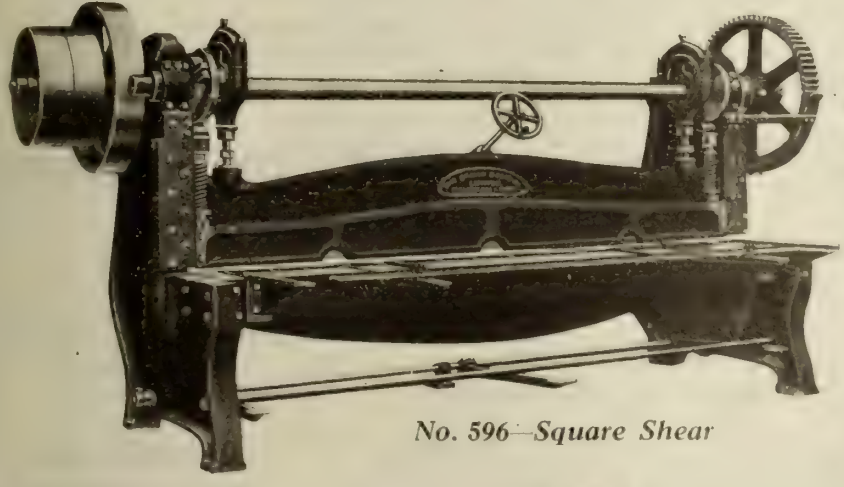
# BROWN-BOGGS

B B



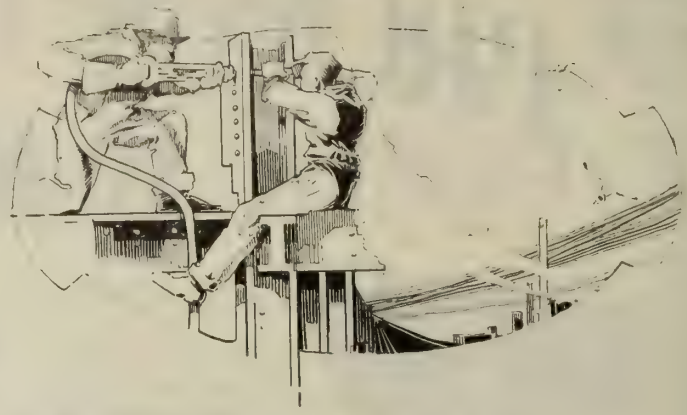
*No. 215—Power Press*

The Sheet Metal Workers' Tools shown here are typical examples of B.B. quality and mechanical excellence. Make sure of the Brown-Boggs trade mark—it's a guarantee of reliable service.

*No. 36—Ring and Circular Shear*

WHEN you buy machinery, choose that which has a reputation for giving long, satisfactory service. Every Brown-Boggs product is manufactured from the highest quality materials, by thoroughly competent workmen, in a fully equipped modern plant.

*No. 596—Square Shear*



The "B.B." line comprises tinsmiths' tools and sheet metal working machines of every description; canners' and evaporators' machinery, shears of all kinds, power presses for punching, forming, embossing, blanking, etc.

*Write for complete catalogue.*

## HAMILTON, CANADA.

# The Dependable Character of Dominion Rubber Hose

is the result of its ability to meet exacting conditions. There are two principal reasons why Dominion Rubber System Hose is used by most Canadian industries—first, because of its performance, and second, because our factory keeps abreast of industry's most exacting demands.

# Dominion Rubber System Hose

is designed for every requirement—for conveying liquids, gases, oils, acids, air or steam, at practically any temperature or pressure. When new conditions crop up, we produce special types to meet them. The fact that we do create new types for the Canadian market is evidence that Dominion Rubber System Hose measures up to the requirements of Canada's largest hose users.

Our catalog is a useful and convenient reference in selecting the right type of hose for your particular needs. A copy will be sent free on request from our nearest service banch.

# STEINLE

## Full Swing Side Carriage Turret Lathes

*Standard 24-in. belt driven Lathe. Furnished in 4-in. or 6¼-in. spindle bore, with or without oil pans, and with standard or special tooling equipment.*

## TIME—Floor to Floor—4½ Minutes Each

THE MACHINE was a standard 24-in. Steinle Turret Lathe with 4-in. spindle bore arranged for belt drive, and equipped on turret with boring bars and special overhead bar carrying a turning tool and on cross slide carriage with a special three-cutter tool block.

THE WORK was an 18-in. cast iron gas engine flywheel. The surfaces machined included boring hub with bars, rough turning rim with special overhead bar carrying turning tool, and shaving and facing both sides of rim with a three-cutter tool block on cross slide carriage.

Just one more record of rapid production on a machine designed and built for fast severe service in producing accurate work economically.

And this record is maintained not on one or two pieces, but on lots of several hundred—just steady, consistent production under average shop conditions.

***Do your records compare with this?***

***Why not send us your blueprints and let our Engineering Department determine what can be done on your own work, or ask to have a qualified representative call and go thoroughly into the matter?***

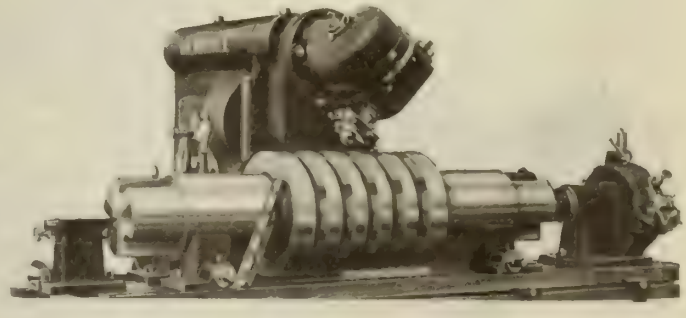
# MILWAUKEE MILLING MACHINES



## Efficient on Light and Heavy Milling

Heavy milling jobs are not unknown to Milwaukee Universal Milling Machines, while delicate and intricate ones are efficiently performed with little effort.

Both light and heavy milling operations are handled with such smoothness and accuracy that the finest results are obtained. Because Milwaukee Universal Milling Machines perform such a wide variety of work, they are particularly well adapted for the tool-room.

The jobs shown in the two illustrations are representative of "Milwaukee" adaptability. The upper illustration shows a jig being bored with a fly cutter. The lower illustrates the milling of a chilled roll with the use of a Universal Milling Attachment.

# *New Method Saves Valuable Hours*

### To Duplicate Blueprints

Tracing them in the drafting room takes hours — sometimes days — of a highly paid man's time, always with a chance of errors.

The PHOTOSTAT accomplishes the same result in a few minutes at a cost of a few cents and without errors.

### To Make Drawings of Small Machine Parts

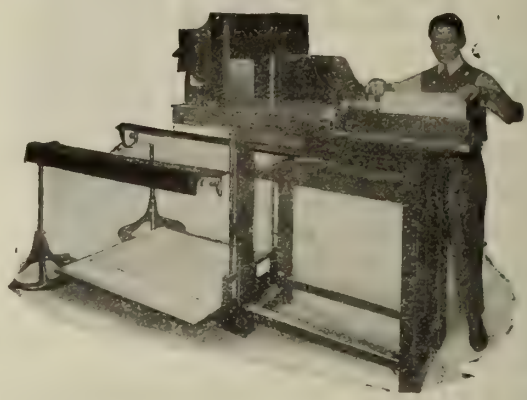
in the drafting room, costs many dollars and takes hours or days of time.

A PHOTOSTAT copy of a small machine part accomplishes the same result and is made in a few minutes at a cost of a few cents.

### To Make Advertising Layouts

by hand for six or a dozen publications requires hours of work by an expensive man.

The PHOTOSTAT quickly duplicates the original layout at the required size and as many times as desired at a cost of a few cents apiece.



### To Copy Catalog Pages

letters, reports, charts, etc., takes hours of a stenographer's time. The results cannot be exact duplicates and there are frequent errors.

The PHOTOSTAT produces an exact duplicate, without errors, in a few minutes, at a cost of a few cents.

## When Friction Disc Grinding

# HEALD STYLE No. 22 EATS 'EM UP

We've always said so but you don't have to take our word for it. Ask the Borg & Beck Co., Chicago, in whose plant the above photographs were taken. They are using three No. 22 Style Heald Rotary Surface Grinders to finish the friction faces of friction discs.

As the top picture shows, these cast iron discs are held on a Heald 12-in. Magnetic Chuck equipped with a special auxiliary top plate. This was cut out in the center to allow the web and hub to drop in when grinding the upper side. Stock removed is .005 to .010 with .003 tolerance. Production is 90 an hour.

*Our Engineering Service Department can, in exchange for blueprints or samples, show you how the Heald can best produce your finished work. A letter helps us both a lot.*

*GRIND WITH A* HEALD *AND BE SURE*

*If interested tear out this page and place with letters to be answered.*

# The Mettle of the Cutting Tool

BASIC steel of proper quality may be the *beginning* of a good tool but it is far from the finished tool that meets the demands of present day practice.

And so it is with heat-treating equipment. The most highly perfected furnace equipment and other materials are handicapped if containers, muffles, racks, etc., crack, warp, scale and change in other ways that interfere with the process.

Cast Nichrome has not only contributed to surer results but is a mighty factor in heat-treating economy. Thousands of hours at 1800 deg. F.—without warping, cracking, scaling, etc.—are guaranteed. Shorter heats and less fuel consumption are inevitable. Stock patterns in hundreds of sizes; special designs for special requirements—

# THE VALUE OF A DIE HEAD IS WHOLLY IN THE SERVICE IT GIVES

# MODERN

"Moderns" have the strength for any duty within the capacity of the 17 sizes. They are widely known as **heavy duty** tools. This strength is not mere mass of metal. Strength comes more from correct design and proper relation of parts, one with another.

The Modern Self-Opening Die Heads are extremely simple. The design is distinctively and exclusively "Modern."

We have no hesitation in stating that a "Modern" will cut more clean, full-size threads, true to lead, and for a longer time without repairs, than any other kind. Hundreds testify to the fact that the "Modern" is the only one which will "stand up" in their work.

If you have a difficult threading job, or would like to speed production, send specifications and blueprints, and let our engineers study your problem.

# Superheat Drills Holes

## *Few "steam metals" can withstand its active chiseling action*

SO in great valves that control superheat flow for vital power production, leading designers call for essential working parts of Monel to withstand high speed gas erosion.

For, of all commercial metals, Monel alone has the ability to survive the combined chemical and mechanical attack of superheated steam at the high and rising pressures commonly used today.

In proof of this, Monel is used for guide stems, wedges, seat rings, spindles, dash pots, piston rings, clappers, piston lock nuts, pistons, etc., in the huge control valves built by Jenkins, Pratt & Cady, Crane and others equally prominent.

Monel is standard for service calling for acid, alkali, high heat and steam wear resistance. It has a prominent place in the specifications of such seasoned engineering organizations as J. G. White, Stone and Webster, Dwight P. Robinson Inc. The name Monel identifies the natural nickel alloy—67% nickel, 28% copper and 5% other metals—produced by The International Nickel Company.

THE INTERNATIONAL NICKEL COMPANY OF CANADA, LIMITED
Harbor Commission Building
TORONTO ONTARIO

THE larger picture is a "close up" of the clapper and seat ring shown in the broken out part of the small valve illustration. The clapper is seen about to lift in order to allow steam to pass into the line. The irregular spurts of steam show that the seat between clapper and ring is no longer perfect—that superheat has commenced to drill its way through. This drilling action is always in process where superheat is used, and the commonly used metals for valve parts eventually fail and allow superheat to cut through. For that reason, Monel is the only safe metal for valve parts that are in constant contact with superheated steam—the only metal that insures always tight valve closure.

# And yet you encourage this!!!!

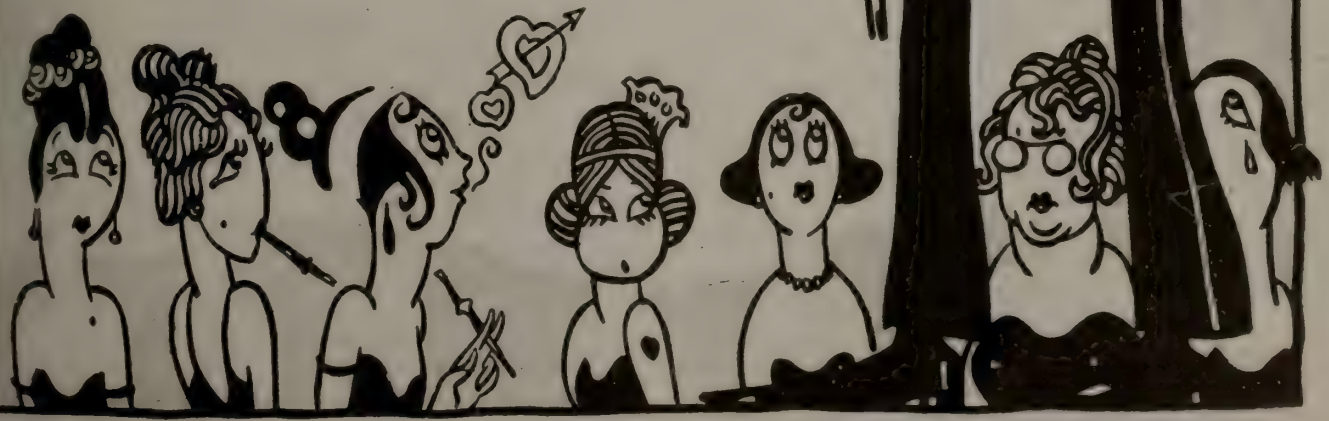
The body of a high speed reamer is the *lounge lizard* of tooldom—it leads a lazy life of expensive ease—while the blades do the work. And *you* support this lounge lizard, *you* pay for its luxury.

And in return it renders you nothing but *brittleness* and *breakage* because even its lazy life is too strenuous for its tender nature.

## PEERLESS HIGH SPEED REAMERS

Peerless High Speed Reamers on the contrary have bodies of a tough stalwart sort of steel—not expensive to support—fully capable of handling the sort of work it has to do—fully able to absorb the shocks and strains which smash a body of expensive high speed steel.

Peerless *blades* however are of high speed steel—especially selected stock treated especially to develop and preserve its cutting powers. The blades and body are then united by a patented process that makes the two one eternal unit—tough where toughness is needed, high speed where high speed is needed.



"Peerless" has no shiftless steel in its makeup—every bit of the tool is ready for the work expected of it—the body for the sudden shocks and strains—the blades for the punishment of high speed reaming—Do you wonder that we dare to ask to—

*Try to Stump "Peerless" On Your Toughest Job.*

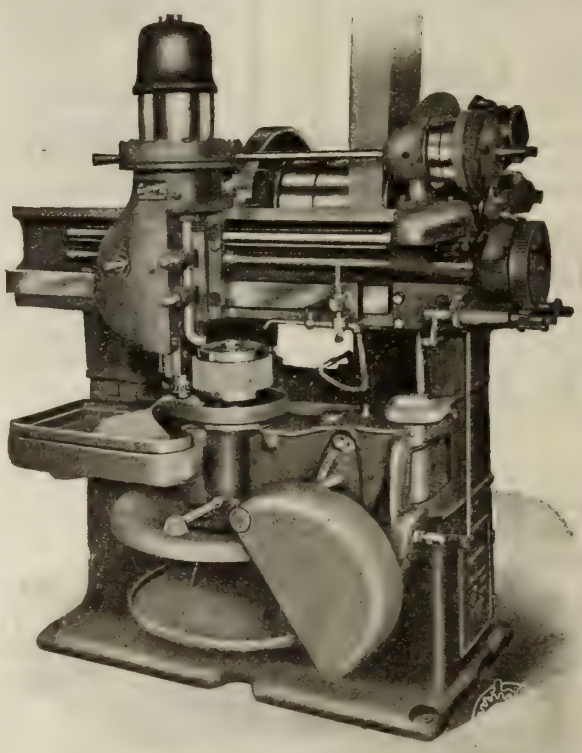
# Gear Cutting With the "IFS" Left Out

## The Gear Shaper Way

A production manufacturer knows that he will secure good gears IF he has an accurate cutter, an accurate machine and a machine working on the correct principle. The whole question of good gears is resolved in this one little word "IF."



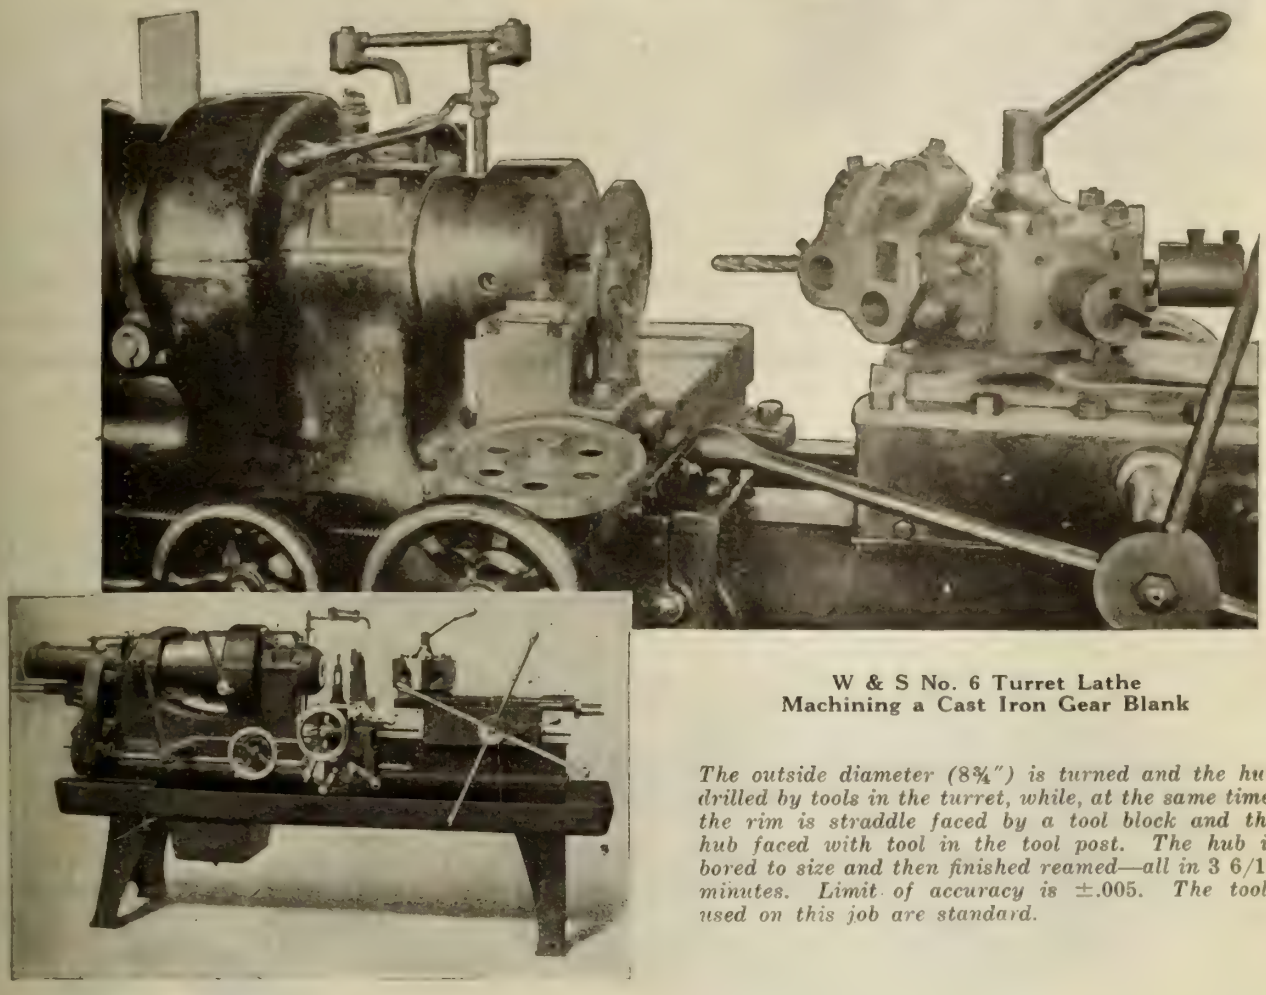
When the Gear Shaper was originally designed, the question of "IF" was taken into consideration and every possible means known to mechanical engineering was employed to eliminate the "IFS" from gear cutting.

That we have been successful in solving the problem is evidenced by the fact that each ensuing year sees a larger number of manufacturers adopting the Gear Shaper method.

How the Gear Shaper has accomplished this is clearly explained in our general catalog "Commercial Gear Cutting," which is a treatise on the subject of:—

Gear Cutting with the "IFS" Left Out.

**Send for your copy to-day.**



The Fellows Gear Shaper—the machine which has taken the "IFS" out of gear cutting.

# Repaired in 5 hours

MAINLY through the portability of Prest-O-Lite it was possible to weld the base of this heavy railroad crane in a few moments less than five hours.

That's the usual quick way in which it is possible to weld with Prest-O-Lite and the oxy-acetylene process.

Through the use of Prest-O-Lite it is possible to weld, build up and cut metals without bringing the work to be done to a workshop.

Thus Prest-O-Lite, the Universal Gas with the Universal Service provides the means for moving an oxy-acetylene welding outfit anywhere and everywhere.

You will be interested in the Nation-wide Service of our conveniently located plants and warehouses.

## *Making the Short Haul s-p-e-e-d the Long Haul*

It's only a short distance—from the ground to the floor of a truck—but it's often the difference between profit and loss.

Loading and unloading is merely a matter of lifting and carrying. The FORD TRIBLOC, suspended from a roller-bearing trolley on a small I-beam trackway, will do the "Short Haul" speedily, safely, economically—and require the services of but one man.

A cut stone manufacturer found it a saving to use his TRIBLOC at both ends of the Haul. A truck is a heavy investment—its idle time loading and unloading might more than pay *you* for a rigging of this kind. Want to know more about it?

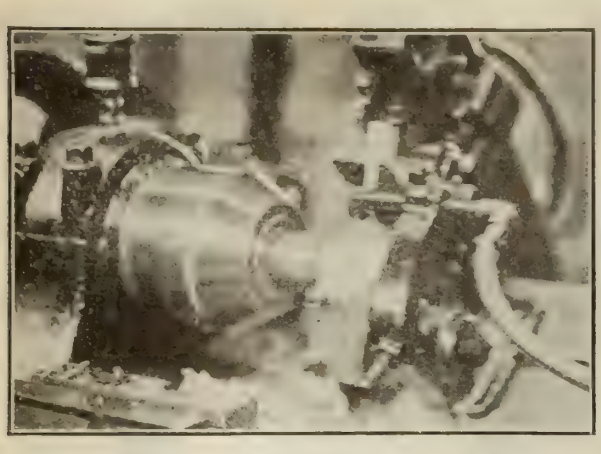
## The "PINK" Line Logging Tools and Handles

**MADE-IN-CANADA Products---Headquarters for British Empire for all Lumbering Tools**



In every lumber camp in Canada you'll find PINK'S famous lumbering tools. They are the favorites there and have won the esteem of all woodsmen through their superior merit. They are world-renowned and are extensively used in Australia, New Zealand and other countries where the lumbering industry thrives.

**EXPORTERS TO EUROPE**

We export the same good quality of lumbering tools that have made PINK'S TOOLS a by-word in the matter of good tools in all Canadian lumber camps. Enquiries cordially solicited.

**Thomas Pink Co., Limited**

PEMBROKE, ONT., CANADA

# LARCUL CUTTING OILS SAVE TOOLS

Tools that ordinari y have to be reground every two or three hours can be kept in use continuously for long periods when cooled with Larcul.

No other lubricant carries the heat from the cutting edge of the tool so rapidly—hence no other lubricant enables the tool to retain its cutting power for such long stretches of time.

The saving in tools alone, in shops that use Larcul, is a big item, not to mention the saving of time made possible by eliminating frequent stops for re-grinding.

The quality of the work, too, is improved by Larcul. Greater accuracy—finer finish. From every standpoint Larcul is the coolant of highest economy and efficiency.

### LARCUL EBONY

Many users claim that they get better results with this oil than they formerly got with lard oil. Recommended for pipe and bolt threading, nut tapping, turrets and automatic forming, turning, boring and threading machinery. On open hearth, low and high carbon steel.

### LARCUL AMBER

A transparent cutting oil that gives an even smoother finish than lard oil. For all types of automatics, turret machines, gear cutters, hobbing machines, broaching machines, nut tappers, profilers, etc., on high carbon, vanadium, chrome nickel and tungsten steel.

# How to Save Money on Hack Saw Blades

Do you "get prices" when you buy hack saw blades? If you do, you are fooling yourself.

The place to save money on hack saw blades is not on the purchasing agent's desk, but in the shop.

Cost per blade has but little or nothing to do with hack saw economy. The blade that will really save money for you may cost a little more per blade, but a great deal less per cut. Figure cost by service rendered and you will realize why so many purchasing agents have changed their specifications from "Star Blades or equal" to "Star Blades—no substitute."

You can use one Star Saw on more kinds of sawing and use it longer.

You have fewer blades to buy; that means you have less money tied up in stock and less chances to run out of sizes.

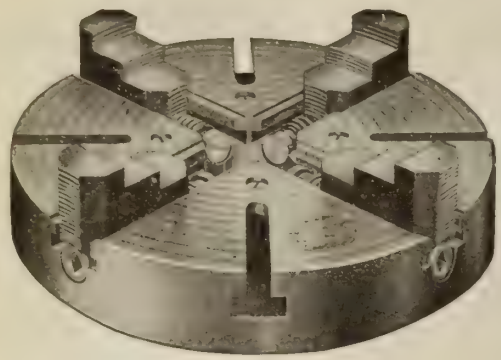
Star Saws are standardized for all kinds of cutting. You can keep a medium-sized blade in your machine and use it for all kinds of work except very large or small cuts.

It all depends on the way Star Saws are made. In Star blades, the greater amount of tungsten and the acute cutting angle of the teeth enable you to go through heavy work almost as easily as light work—the hardest steel as well as the softer metal.

Don't let "prices" fool you. It's the work that the Star does out in your shop that saves you money.

## Star Saws are Now Sold By the Makers

We now sell our own product, for we believe no other organization is in such a good position to give selling service on Star Saws as our own factory that has made them for 37 years.



We are not satisfied only to sell you Star Blades, but stand ready to render you every service in getting the best results in their use.

# Why I Increased My Space in Business Papers for 1921

*—By a Manufacturer*

(1) "Business conditions are fundamentally sound.
(2) "My goods will have to be *sold,* not just bought.
(3) "I propose to cut travelling costs by relieving salesmen of work that advertising can do better and more cheaply.
(4) "My advertising will aid in the restoration of Confidence.
(5) "Increased sales resistance calls for added sales effort.
(6) "Conditions make your papers more indispensable, more closely read.
(7) "I know they reach my market without waste.
(8) "Because they are doing a big, constructive, creative work—benefiting me through promoting the welfare of my customers.
(9) "It is time to intensify sales forces of proven productiveness and low cost.
(10) "I need the business."

**Just Common Sense**

—a good many will say. Nothing here that everyone does not know, but half of wisdom consists in *being wise in time.* This advertiser not only did some clear thinking, but he acted.

TRAHERN
Better Threads
One of the vital necessities for cutting clean and accurate threads, is a steady stream of coolant kept flowing upon the chasers of the die head. The coolant gives longer life to the chasers, keeps them cool, and makes threading much easier.
But a dependable circulating pump is necessary to assure a steady flow of coolant.
Trahern Rotary Geared Coolant Pumps are furnished as regular equipment on leading machine tools to-day. They throw heavy, forceful streams entirely free from pulsation. Supply can be shut off at discharge without stopping the pump, assuring the right quantity of coolant at the proper time. Will pump water, oil or compound. Operate at low speed, guaranteeing long life. If necessary will work against 100 lbs. pressure. When properly installed, guaranteed not to lose their prime.
For high quality threads, equip your machines with TRAHERN Pumps. Our catalog No. 11 explains in detail.

# No. 2 TYPE "R"
# Hartness Automatic Die

***WITH SHANK FOR REVOLVING SPINDLES***

These dies are designed for use on either vertical or horizontal spindles. Die is re-locked by forward motion of sleeve, which may be actuated by a yoke working in the groove or by a fixed stop making contact with rear edge of sleeve at the return stroke. Die is unlocked in the usual manner by retarding its forward motion or by a fixed stop, making contact with the external tripping button shown on the face of the die. External tripping button is especially desirable in cutting very short threads as it relieves the thread of the strain incidental to unlocking by the pull-off device.

**The diameter of the No. 2, Type R die is 3 3-16 in., and its length as shown is 3½ in.**

**The Die cuts both right and left-hand threads ½ in. to 1 in. in diameter, and from 10 to 40 threads per inch.**

**Shanks are varied to meet individual requirements.**

**A set of standard chasers in carbon steel is supplied gratis with each Die.**

**No tools of any kind need be used in changing chasers.**

**A chaser grinding jig is supplied gratis on Die orders if desired.**

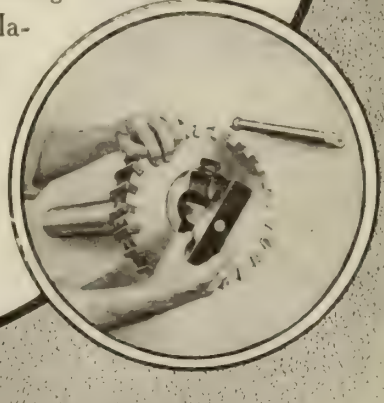
# BROWN & SHARPE TAPER-NOSE SPINDLE



*No Screws Plates or Loose Parts*

THE TAPER-NOSE SPINDLE . . .

assures a positive cutter drive under all conditions. The front end of spindle is tapered, hardened and ground and has a recess to receive cutter driver and clutch on arbors and collets. The ease with which face milling cutters are removed and replaced is particularly noteworthy—simply place cutter onto the taper nose of the spindle, insert cutter drive as shown in the illustration and tighten drawing-in-bolt. There are no plates, screws or loose parts used and when arbor, collet or cutter is in place it is essentially as firm as though a part of the spindle itself. This is one of the many outstanding features of Brown & Sharpe Milling Machines. For further information send for our Milling Machine Book.

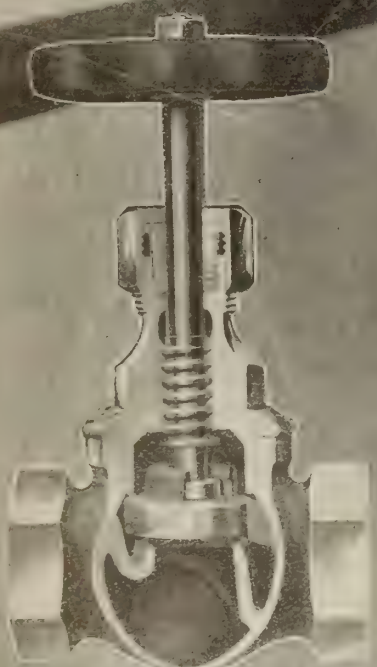
## An Achievement in Mechanics



EACH individual department of The Canadian Fairbanks-Morse Company, Limited has given industrial Canada a new conception of achievement in mechanics. Each department has established a 100% quality and service standard. This is what enables Fairbanks valves to stand pre-eminent wherever valves are used.

When an engineer specifies Fairbanks valves, he knows that he has selected not only quality of material but workmanship that guarantees perfect operation.

He is satisfied with the reputation and service of the institution that stands behind them. He acknowledges an achievement in mechanics.

Wherever pipe lines are laid—in Canada's great industrial plants—in her immense water systems—in mines and mills—Fairbanks valves are giving a service that is marked by the 100% seal of quality, the standard of The Canadian Fairbanks-Morse Co. Limited.

Our nearest branch will give you the benefit of this service, Our experts will help you in selecting valves and everything mechanical that you require. Make our catalogue your buying guide.

CANADIAN MACHINERY
AND
MANUFACTURING NEWS

VOL. XXV. No. 5 February 3, 1921

# Turret Lathe Applications

Careful planning of tool layout is necessary to ensure maximum production. The layouts, in this, the first of a series of articles on turret lathe practice, show how to machine a truck wheel, an automobile flywheel, and another flywheel of unusual design.

*By J. H. Moore*

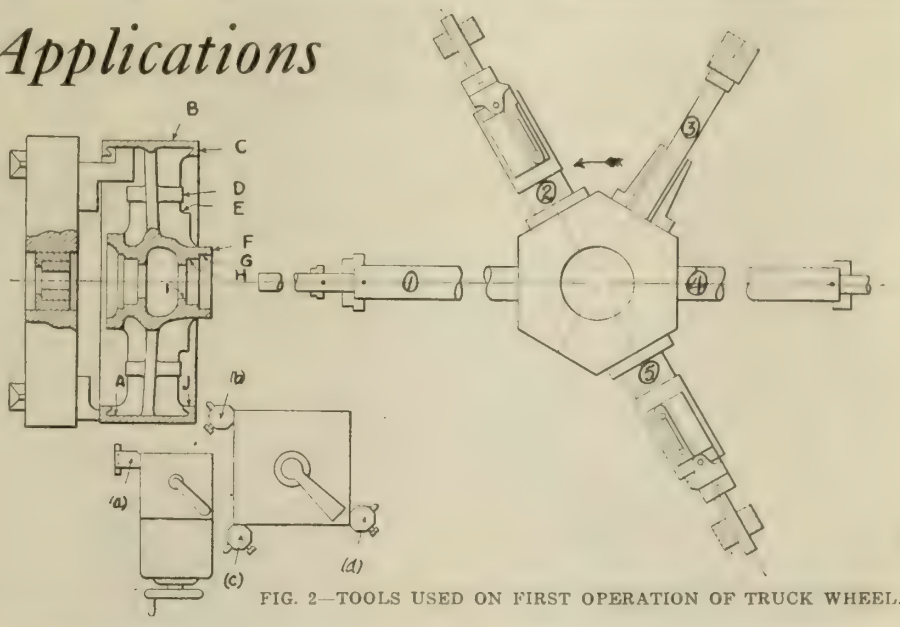

FIG. 2—TOOLS USED ON FIRST OPERATION OF TRUCK WHEEL.

THE subject of turret lathe work is always interesting, especially in these days when production is [illegible]. A turret lathe, irrespective of its design, cannot accomplish its best [illegible] if improperly tooled. It is therefore perfectly safe to say that proper tool layout is just as important, if not more so, than the machine itself. A good machine can be rendered of very little value by the use of poor tools. Believing the readers of Canadian Machinery are interested in the subject of tool layout, we have prepared a series of articles, each complete in itself, dealing with this important matter. The information embodied in these articles was secured at the plant of the Gisholt Machine Tool Co., Madison, Wis., and deals with various parts produced on their machines.

### Auto Truck Wheels

The first example is that of a truck wheel shown at Fig. 1. This view details the design of a rear wheel used on an automobile truck. The heavy lines indicate finished surfaces, that is, the surfaces finished in the turret lathe. This example is especially interesting, because the auxiliary tool post, commonly known as the wing rest tool post,

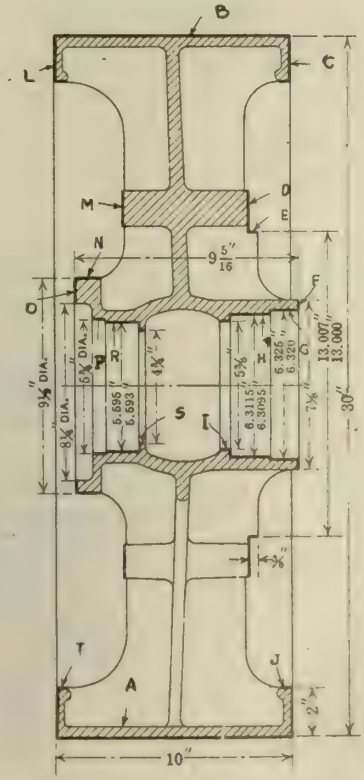

FIG. 1—DETAIL VIEW OF THE TRUCK WHEEL.

is brought into action. It might be well to add that all Gisholt turret lathes have an extension on the carriage for this tool post, so that it can be used whenever required. This auxiliary post is especially useful when turning diameters which are too large for the regular tool post. Of course, this post also provides for additional permanently set tools should the operation lend itself to their use. As a general rule, this auxiliary is not necessary, but it's good to know it's there if you require it.

Referring once more to the drawing of the wheel. The work is finished in two operations, the tool layout for the first operation being shown at Fig. 2. It will be noted that the wheel is held from the inside of the rim by means of special hardened jaws A, and is located by means of special blocks on the chuck. The outside surface B of the wheel is next rough turned with the tool (a) which is held in the auxiliary tool post. The surfaces C, D, E, and F are now rough faced with tool (b) in auxiliary tool post.

The holes G, H, and I are next bored with cutters held in the boring bar mounted in position 1 of the turret. This bar is provided with a pilot, guided by a bushing in the chuck of the machine.

The surface H is now finish bored by a cutter held in position 4 of the turret, this bar being guided in the same manner as the bar already described.

The hole H is reamed out with the reamer in position 3 of the turret, and the surfaces E and F are rough turned by means of cutters held in the facing head at position 2 of the turret. The tool working on surface E is held in the top arm, and the tool machining F is held in the bottom arm of the facing head.

The surfaces E and F are next finished with tools held in the facing head at position 5 of the turret. This facing head is exactly similar to that used for the roughing operation.

Next come the surfaces C and D, these being finished with the tool (c), see auxiliary tool post. The inside of the rim at J is bored with the tool (d) also held in the auxiliary tool post. The total time for these various steps in 50 minutes.

### Second Operation

We now come to the second step. This is shown clearly at Fig. 3, and the following steps are gone through. The work is held on a special chuck plate by means of clamps. The surfaces L, M, N, and O are rough machined with the tool (a) held in auxiliary tool post. The holes P, R, and S, are next rough bored with cutters held in position 1 of the turret. This bar has a pilot which is guided in a bushing mounted in the chuck plate.

The hole is now finish bored with the cutter held in boring bar at position 2 of the turret, this bar being piloted as stated previously. This same hole is next reamed with a reamer mounted at position 3 of the turret. A second roughing cut is now taken over the outside of the wheel by means of tool held in the auxiliary tool post, this cut being followed by the facing head mounted at position 5 of the turret. This head finishes the outside of the rim also the surfaces N and O. The three tools necessary to complete this work are mounted in the top, rear, and bottom arm of head respectively.

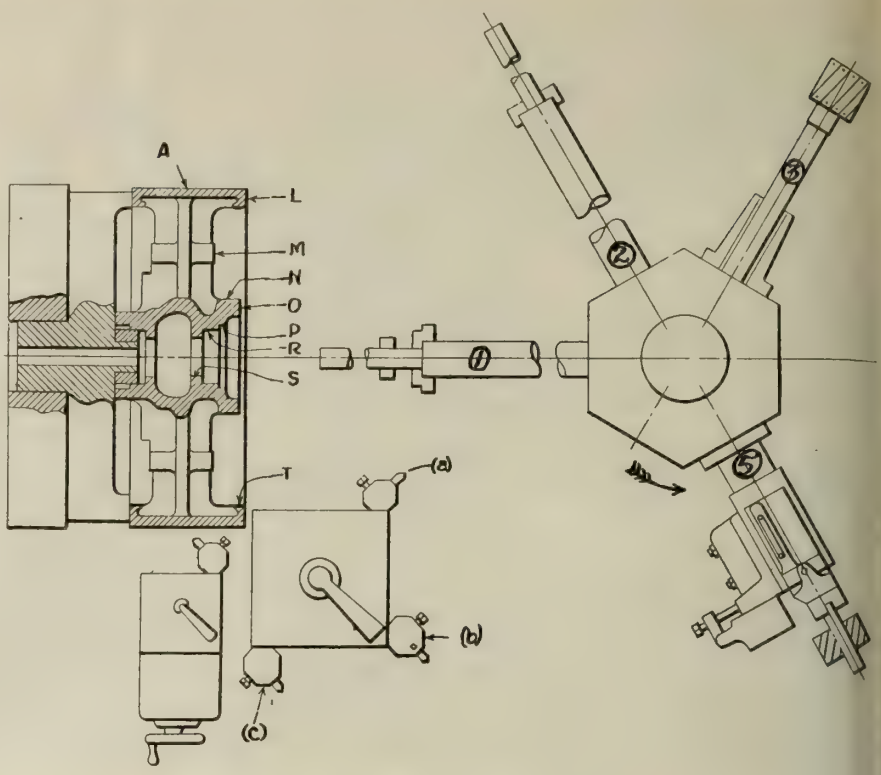

FIG. 3—SECOND OPERATION ON THE WHEEL SHOWN AT FIG. 1.

While this operation takes place, the facing head is guided by means of a bushing on its pilot which enters the hole R. The surfaces L and M are next finished with the tool (b) in auxiliary tool post. The inside of rim is now bored with the tool (c) in tool post. The total time required for these steps is 45 minutes.

Figs. 4 and 5 show up to good advantage the two operations in photographic form. The auxiliary tool post is plainly seen in each case, and as the steps have already been described in detail we need not dwell on these views.

### Automobile Flywheel

The next example of work perfor d is shown at Fig. 6. This represents a automobile flywheel made of semi-st l on which the sections are rather t n. In finishing this piece, three operati s in place of two are necessary, as a gr at amount of stock has to be remo d. As the sections are very light con l- erable distortion would result if all t e stock was removed at once on each f e of the wheel. In a case of this kind i s good policy to have one, or even m r extra operations, rather than allow d tortion.

### First Operation

The first operation consists of ro h ing one side. The other side is rou h

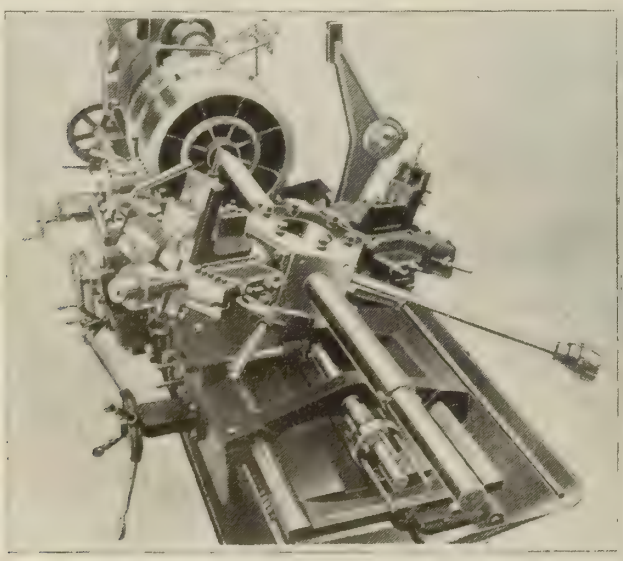

FIG. 4—TOP VIEW OF EQUIPMENT USED ON THE FIRST OPERATION OF TRUCK WHEEL SHOWN AT FIG. 1.

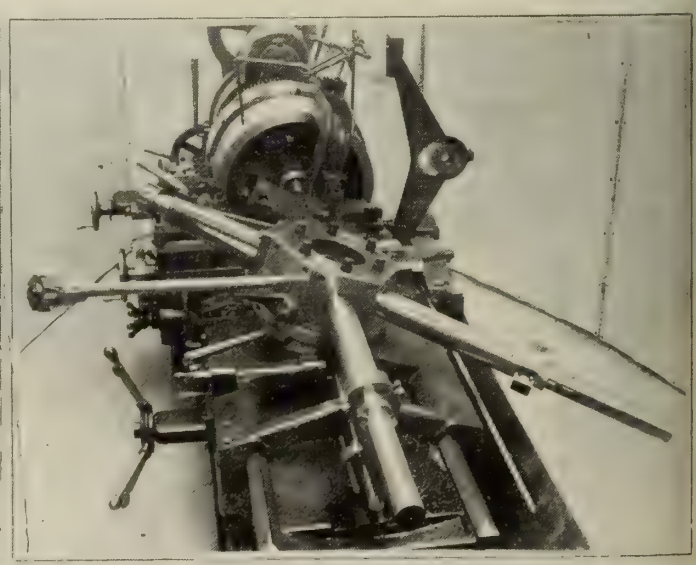

FIG. 5—A SIMILAR VIEW SHOWING THE TOOLS USED ON THE SECOND OPERATION OF THE TRUCK WHEEL.

ad finished in the second operation, vile the flywheel is rechucked in the trd operation, and the first side, which i only roughed, is next finished. Fig. 7 illustrates the tool layout for the first eration. The rough turned flywheel, ai the method employed to hold the sne is shown at Fig. 8. Following are t steps in the first operation.

The work is held in special hardened cick jaws, and the bottom A is rough fed with tool B in tool post, and the he is bored with the cutter mounted at p ition 1 of the turret. The inside and o side surfaces C and D are next bored ai turned respectively, with the facing h d mounted at position 3 of the turret.

The head shown at position 6 of the tret is now used, but is merely mounte to balance the turret.

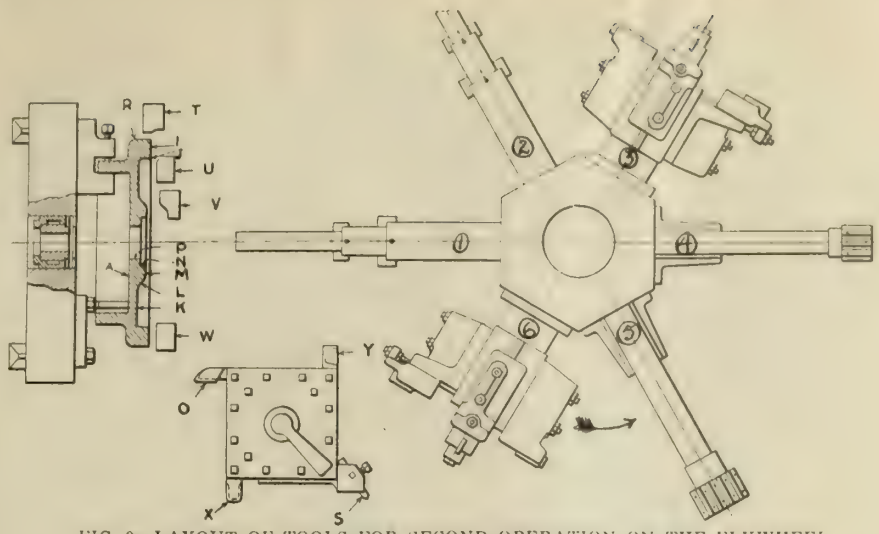
The surfaces E, F, and G are now r gh faced with the tool H in the tool pt. This first operation is completed in minutes.

**Second Operation**

The work is held in the second operati as shown at Fig. 9. At this operati the one side of the flywheel is roughe and finished complete, and the steps p formed are as follows. The work is h l in special jaws as indicated, and clck jaws are used to support it against th surface A. The surfaces I, J, K, L, a M, also the bottom of the counterbe N are rough faced by the tool O ir he tool post.

fter this is accomplished the bore P nd counterbore N are rough bored w cutters in the bar mounted at positi 1 of the turret. This same bore a counterbore is now finished with the ers in bar mounted at position 2 of th turret. The bars used in these steps ar provided with pilots that enter into a ushing in the chuck.

ne bore P is next reamed with the rener mounted in position 4 of the tret, after which the outside surface



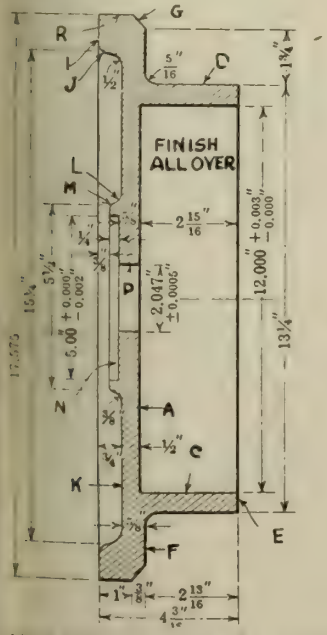


FIG. 9 LAYOUT OF TOOLS FOR SECOND OPERATION ON THE FLYWHEEL SHOWN AT FIG. 6.

FIG. 8 SHOWING THE METHOD OF HOLDING FLYWHEEL IN THE FIRST OPERATION.

IG. 6 DETAILS OF THE AUTOMOBILE FLYWHEEL.

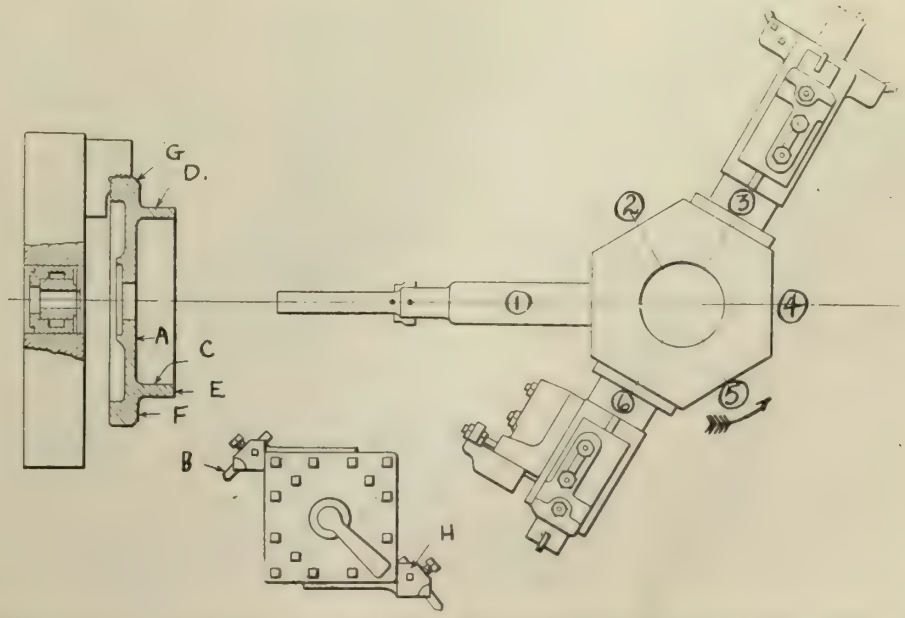

FIG. 7—LAYOUT OF TOOLS FOR THE FIRST OPERATION ON THE FLYWHEEL SHOWN AT FIG. 6.

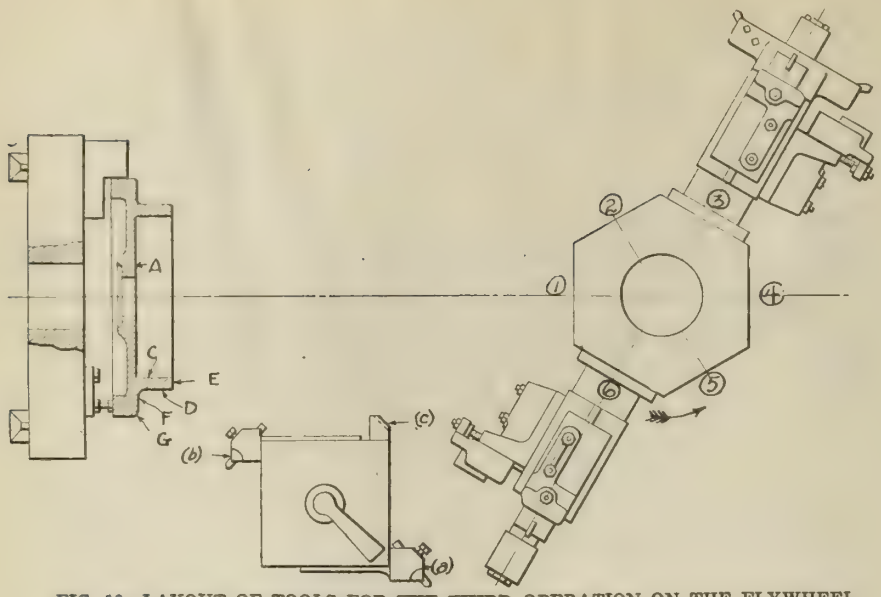

FIG. 10—LAYOUT OF TOOLS FOR THE THIRD OPERATION ON THE FLYWHEEL.

R is rough turned with tool S mounted in the tool post. This tool is followed by the facing head mounted in position 3 of the turret. This head roughs the surfaces R, I, J, and M. The facing head is provided with a pilot entering the bore of the flywheel. The tool T which turns the surface R is held in the top arm, while the cutter U is held in the front arm of facing head. The cutter V is held in the bottom arm, and cutter W in the rear arm of the same head.

The surfaces R, I, J, and M are now finished by the tools of similar nature. The surfaces K and I are finally completed by means of tool X held in the tool post. The bottom of the counterbore N is finished by tool Y held in the tool post. The cylindrical surface of the counterbore N is finished by reaming with the reamer shown at position 5 of the turret. The total time for this second operation is 10 minutes.

### Third Operation

Fig. 10 depicts the third and last operation on this piece. This work consists of finishing the already rough finished side of the wheel. The work is followed out in this manner. The flywheel is held with soft jaws, and is supported by means of chuck jacks. The outside of the cylindrical surface D, and the face F are rough faced by the tool (a) in the tool post.

The surfaces C and E are rough machined, and the surfaces D and F are finished with tools in facing head at position 3 of the turret. This facing head is piloted in the bore of the flywheel. The bottom A is finish faced with tool (b) in the tool post, after which the surfaces C and E are finished with cutters held in the facing head at position 6 of the turret. It will be noted that these tools are directly opposite, this being, of course, to balance up the turret.

The chamber G is finished with tool C in the tool post, and the total time for this, the final operation is ten minutes. This makes a total of 28 minutes for the three operations.

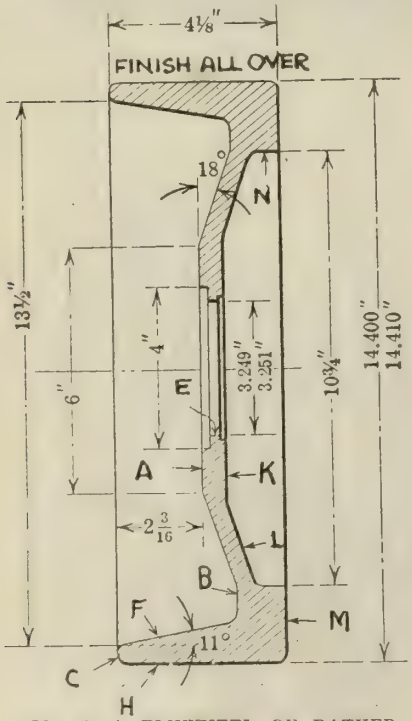

FIG. 13 -A FLYWHEEL OF RATHER UNUSUAL DESIGN.

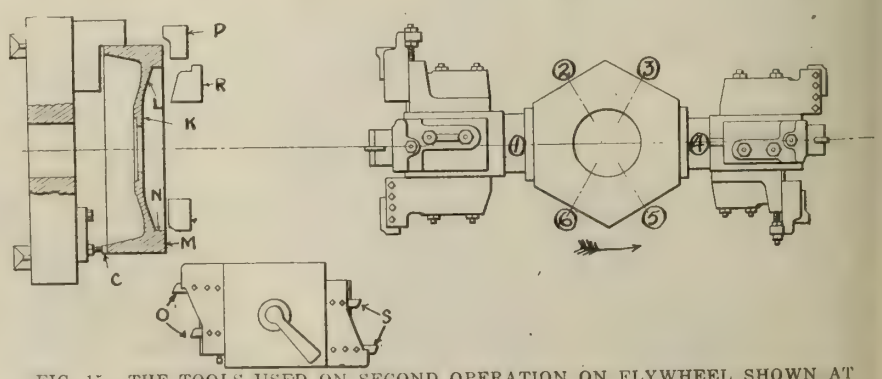

FIG. 15. THE TOOLS USED ON SECOND OPERATION ON FLYWHEEL SHOWN AT FIG. 13.

### Flywheel of Unusual Design

The remaining example in the presen article is shown at Fig. 13. This viev depicts another flywheel, but one whicl has a most unusual design. It will b noted that this wheel has central web part of which is at an angle with th axis of the flywheel. The material i cast iron, and the wheel is finished al over on a 24 inch turret lathe in tw operations.

The first operation consists of rough ing and finishing the convex side of th web, the beveled inside surface, and th outside of the rim. Fig. 14 illustrate the tool layout for the first positior The work is held by the inside of rim b means of special chuck jaws. The sur faces A, B and C are roughed with th tool D in the tool post. The hole E i next bored, and the surface A is finis faced with tools mounted in position 1 ( the turret. The tool is guided by a pil which enters a bushing in the chuck.

The hole E is now reamed with th reamer held at position 3 of the turre The bevelled surface F is next roug bored with the tool in the facing head a position 4 of the turret. Simultaneousl with this operation, the outside H ( the wheel is rough turned with the to G in the tool post. The beveled surfac F is now finished with the tool held i the facing head at position 2 of th turret.

Following this step the surfaces C an B are machined, and the corners of su faces C are chamfered with the too at position 5 of the turret. The facin head used for this work can be clearl noted in the photograph shown at Fi 16. This tool is specially designed finish the tapered surface F with a sing point tool. In this way the angle bound to be correct. In action here what occurs: A pilot enters the bore the flywheel, and a flange is provide with a ball thrust bearing which bea against the web of the wheel at C. Th locates the tool accurately, and prevent the pilot from entering beyond a ce tain point. The head then slides ov the pilot, and as the head is provide with a pin that rests against a taper surface immediately beyond the thru bearing, the tool in the facing head lowered as it slides forward, thus e suring that it will finish the surface a

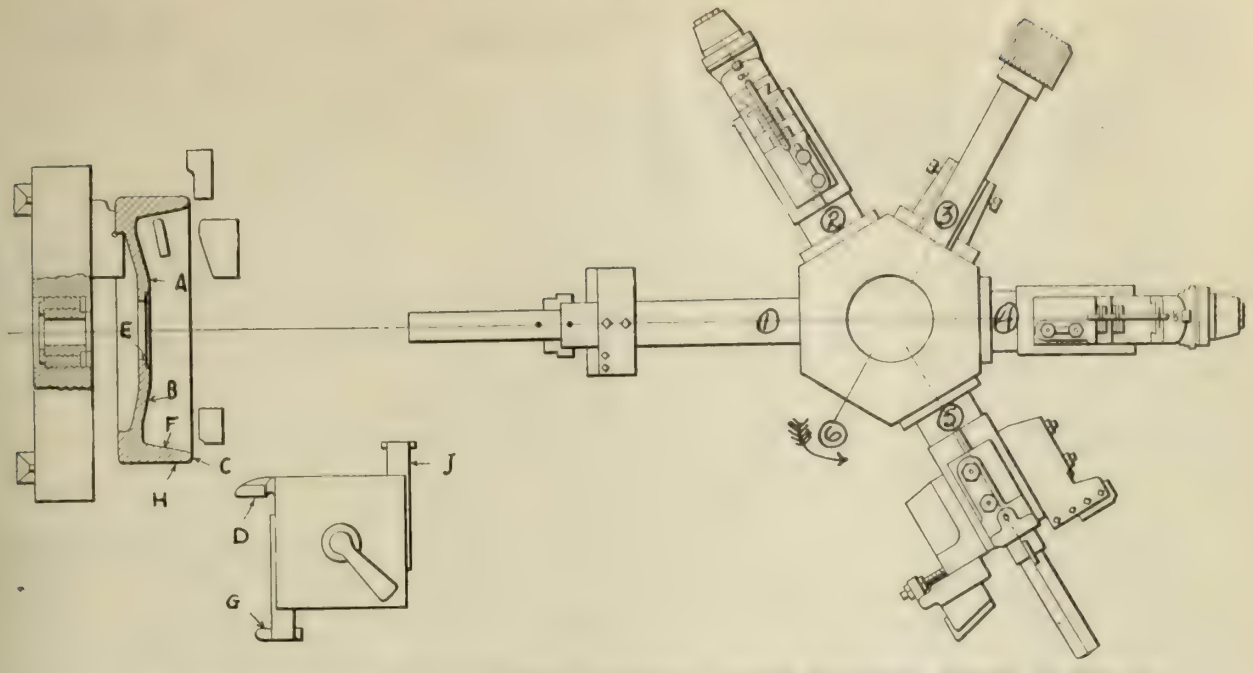

FIG. 14 TOOLING USED FOR THE FIRST OPERATION ON THE FLYWHEEL SHOWN AT FIG. 13.

curately. The last step in the first operation consists of finishing the outside surface H with the tool J in the tool post.

### Second Operation

The second operation is shown at Fig. 15. This consists of roughing and finishing the concave side of the fly wheel, and the method employed is as follows. The work is held in soft chuck jaws which bear against the finished outside surface of the flywheel. It is also supported by means of chuck jacks which bear against the rim at C.

The surfaces K, L, and M are now rough faced with tools held at O in the tool post. The surface N is next rough bored, and the surface L is rough faced. The outside corner at N is also rounded with tools held in the facing head at position 1 of the turret. The surfaces N and L are now finished, and the inside corner of N is rounded with the tools held in head at position 4 of the turret. In both the third and fourth steps, the facing heads are piloted in the bore of the flywheel. The tool P is held in the rear arm of facing head, while the other R is held in the top arm. The last step is that of finishing the surfaces K and M by means of the tool S in the tool post. Fig. 17 depicts the second operation, as viewed from the front of the machine.

This completes the present article. In a later issue we will show further examples of work performed on these styles of lathes.

### PROPERTIES OF METALS

An investigation into the properties of white metals for bearings has recently been carried out by the Bureau of Standards. It was found that tin-base alloys maintain their strength properties better at elevated temperatures than do those containing lead. However, the yield point or ultimate strength of a high-grade babbitt at either 25 deg. or 75 deg. Cent. is not affected by lead admixtures up to 3 per cent. Prolonged heating lowers the strength of lead-base alloys much more seriously than it does that of tin-base alloys. The yield point of a tin-base alloy was not affected by heating for six weeks at about 100 deg. Cent., but the yield point of a lead-base alloy was lowered by only two weeks' heating at the same temperature.

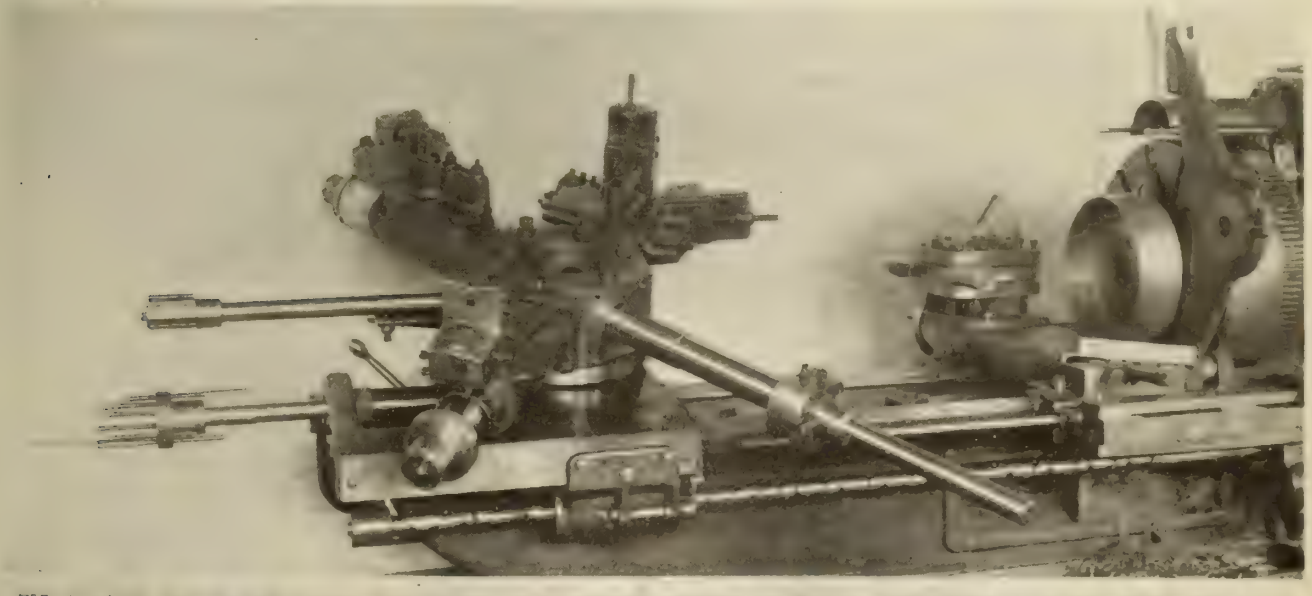

FIG. 17.- THE SET UP FOR FIRST OPERATION ON FLYWHEEL SHOWN AT FIG. 13. THIS VIEW IS TAKEN FROM THE REAR.

# The Side-Cutting of Thread Milling Hobs

## The Hobbing of Screws, Interference Due to Helix, and Other Important Formulae—Points Out the Corrections in the Form of Thread Milling Hobs Which Can Readily Be Made

*By E. BUCKINGHAM

WHEN a thread is chased in a lathe and the cutting tool has proper clearance and is set so that the plane of the cutting edges contains the axis of the thread, the exact form of the tool will be duplicated on the work. Assuming that the thread is completed, if the tool in its cutting position is brought into contact with the flanks of the thread, it will have a line bearing only. If sufficient clearance can be provided on the tool, this holds true regardless of the pitch of the thread, the angle of the flanks, or its diameter.

When a thread is hobbed, however, the axis of the hob being parallel to the axis of the thread, the path of any one cutting point is a circle, and this circle will interfere with the helix of the thread to an amount depending upon the pitch of the thread, the angle of the flanks, and the diameters of both hob and thread.

It is assumed in this discussion that the cutting teeth of the hob are backed off sufficiently to prevent any dragging of the relieved portion of the tool on the work. The interference between the cutting edge of the hob and the helix of the thread therefore results in the removal of additional metal, thus distorting the form of the thread. The amount of this distortion varies as the values of any of the following factors change: the pitch of the thread, the form of the thread, the diameter of the work, and the diameter of the hob.

*The author is Engineer of Standards for Niles-Bement-Pond Co., and Pratt & Whitney Co. He is an associate member A.S.M.E. This is an abstract of his paper presented at the annual meeting, New York, of the American Society of Mechanical Engineers.

It will be shown that correction for some of this distortion inevitable with this method of manufacture is impossible. The amount of this distortion, however, can be reduced in many cases by the proper relation between the diameters of work and hob. It will also be shown that most of the distortion can be corrected by a suitable alteration in the form of the cutting tool.

### The Hobbing of Screws

In Fig. 1, which shows a diagram of a hob and screws, let

R=radius of any cutting point on the hob

r=radius of deepest point on work touched by R

N=number of threads per inch

A=angle of rotation of hob

B=angle of point of contact of R at angle A

C=½ included angle of thread

r′=radius of point of contact on R on work.

Formulas will first be derived to show the interference between the path of any cutting point on the hob and the flanks of the thread and for purposes of plotting the radial distance of the cutting point R from the deepest point on the work touched by R will be designated as y. In other words,

$$y = r' - r \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad (1)$$

The longitudinal (or axial) distance R of the cutting point from the flank of the theoretical thread will be designated by x. A plus value of x will indicate a clearance, while a minus value will indicate an interference or side-cutting.

In order to determine the value of y the triangle shown in heavy lines in Fig. 1 must be solved. The known factors will be taken as r, R and B. We first have

$$\frac{(R+r)\sin B}{R} = \sin 180° - (A+B)$$

$$\sin 180° - (A+B) = \sin (A+B)$$

$$\frac{(R+r)\sin B}{R} = \sin (A+B) \quad \ldots \quad (2)$$

From this equation we determine the value of A. Solving the triangle for r′, we have

$$r' = \frac{R \sin A}{\sin B} \quad \ldots\ldots\ldots\ldots \quad (3)$$

and when the value of r′ is determined, the value of y is established from Equation [1].

As the hob revolves away from the common center line of the hob and work, the cutting points on one side of the tooth of the hob, due to the helix of the thread, will have a clearance with the flank of the thread, while the cutting points on the other side of the tooth of the hob will develop an interference. But the side of the hob which clears the helix as the cutting point revolves away from the common center line will interfere as the cutting points approach to the common center line, and the nature and extent of this interference will be symmetrical and equal on both flanks of the thread as long as the form of the thread is symmetrical.

The amount of interference depends upon the value of B and the pitch of the thread, or number of threads per inch, N. Thus

$$\text{Interference Due to Helix} = \frac{B}{360N} \quad \ldots \quad (4)$$

If the included angle of the flanks of the thread is greater than zero (which is the case for all but square threads), as the cutting point of the side of the cutting tooth departs from the common

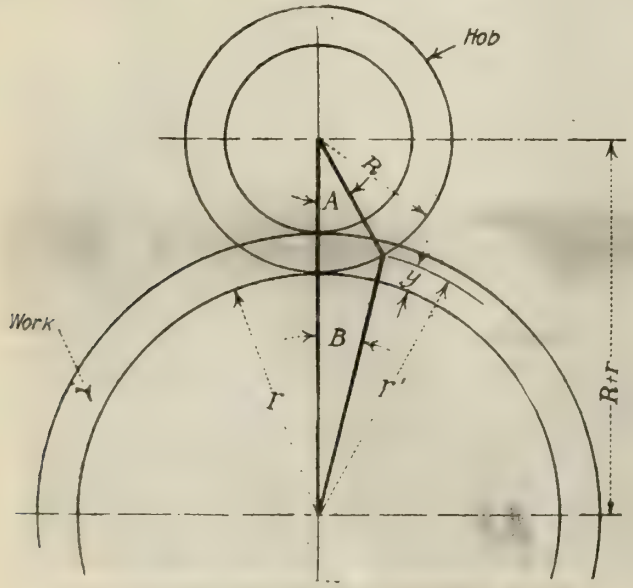

FIG. 1—DIAGRAM OF HOB AND EXTERNAL SCREW.

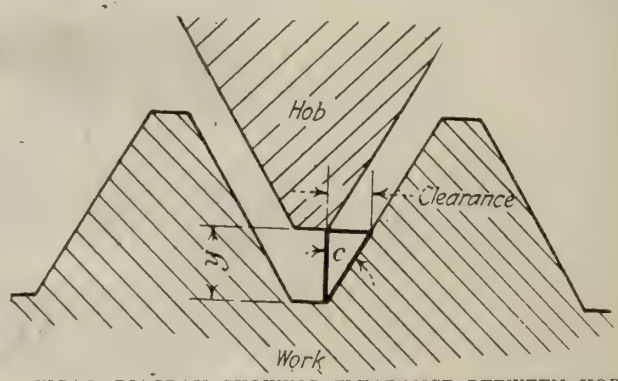

FIG. 2—DIAGRAM SHOWING CLEARANCE BETWEEN HOB AND WORK.

centre line of the hob and work a clearance develops between the cutting point on the hob and the flanks of the thread. The amount of this clearance depends upon the value of y and the included angle of the thread, and referring to Fig. 2 it will be seen that its value, ignoring for the present the helix of the thread, may be expressed as:

$$\text{Clearance} = y \tan C \quad \ldots\ldots\ldots\ldots [5]$$

The value of x is therefore found by subtracting the amount of interference given by Equation (4) from the amount of clearance given by Equation (5), or

$$x = y \tan C - \frac{B}{360N} \quad \ldots\ldots (6)$$

As an example of the use of the above formulae, we will assume that we wish to hob a thread which has a radius r or 0.5625 in. at the minor diameter with a hob whose radius R is 2.250 in. at its outside diameter with 4 threads per inch. A thread with a relatively large helix angle is taken as the first example in order to show the nature of the resulting side-cutting of a hob. The thread has an included angle of 60 deg., making C=30 deg., and N=4. The value of B is taken from 0 deg. to 12 deg., which gives the following values for x and y:

| For B = 0° | 2° | 4° | 6° | 8° | 10° | 12° |
|---|---|---|---|---|---|---|
| x = 0 | —0.00114 | —0.00176 | —0.00194 | —0.00157 | —0.00064 | —0.00084 |
| y = 0 | 0.00043 | 0.00176 | 0.00386 | 0.00691 | 0.01092 | 0.01589 |

The above as well as intermediate values are plotted in Fig. 3-A at the left, and the actual path of the cutting point is shown at the right. These curves show the general form of the side-cutting of any point on the cutting face of a thread hob.

This cutting face of the hob is made up of an infinite number of points. As the positions of these points vary, the ratio between R and r varies, as also does the helix angle of the thread, and therefore each cutting point travels in a different form of path. Thus, in order to determine the resulting form of a thread cut with a hob it will be necessary to plot the paths of a few other points. A point 0.20 in. higher on the flank of the thread will therefore next be taken. This gives R=2.050, and r=0.7625, as before, C=30 deg. and N=4, and the values for x and y with these factors are as follows:

| For B = 0° | 1° | 3° | 5° | 7° | 9° |
|---|---|---|---|---|---|
| x = 0 | —0.00061 | —0.00126 | —0.00117 | —0.00032 | —0.00136 |
| y = 0 | 0.00015 | 0.00143 | 0.00398 | 0.00786 | 0.01318 |

These values are plotted at the left in Fig. 3-B. The actual path of the cutting point is shown at the right.

A third point 0.40 in. above the bottom of the thread will also be taken. This point is beyond the top of the thread, but it is taken to accentuate the distortion developed by hobbing. In this case R=1.85, r=0.9625, C=30 deg., and N=4. The values for x and y with these factors are as follows:

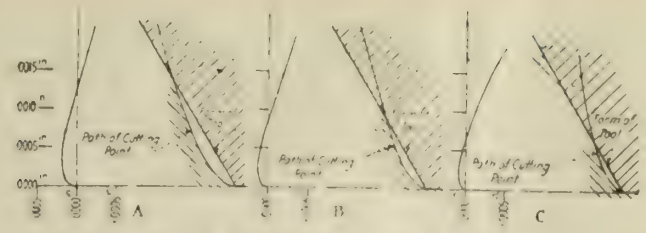

FIG. 3 CURVES SHOWING PATHS OF CUTTING POINT.

| For B = 0° | 1° | 3° | 5° | 7° |
|---|---|---|---|---|
| x = | —0.00057 | —0.00093 | —0.00026 | —0.00151 |
| y = 0 | 0.00022 | 0.00199 | 0.00566 | 0.01104 |

The above values are plotted at the left in Fig. 3-C. The actual path of the cutting point is shown at the right.

In order to show more clearly the nature of the side-cutting of hobs, the curve in Fig. 4 is plotted in an exaggerated form with the intervals along the y-axis equal to 0.001 in., and those along the x-axis equal to 0.0001 in. The curves shown in Figs. 3-A, 3-B and 3-C are plotted to this scale and brought together proportionately; that is, the origins of these curves are spaced equally from the bottom, but these spaces are not to scale. This distorts still further the exact shape of the curve, but its general properties are quite correct.

This curve shows the general nature of the distortion in the form of a thread which is caused by the side-cutting of the hob. It will be noted that it is a double curve, the lower part (below the line A-A) being developed by the bottom corner of the hob tooth while the upper part (above the line A-A) is developed by the overlapping paths of successive cutting points on the cutting face of the hob. It is evident that the distortion shown at the bottom of the curve is inevitable and no correction in the form of the hob is possible that will eliminate it. It can be reduced in many cases, however, by making the hob smaller in diameter. On the other hand, the distortion shown in the upper part of the curve can be eliminated by changing the form of the cutting edge on the hob.

The correction of the hob is determined in the following manner: The greatest amount of side-cutting is done by the bottom corner of the hob. In the foregoing example the tabulation shows 0.00194 in. when B=6 deg. This is not necessarily the exact maximum. If a closer value is required, the tabulations must be made with increments of B of smaller amounts. Tabulations as shown, however, will be correct to the fourth decimal place, which is sufficiently accurate for most purposes.

If the tooth of the hob is narrowed at each point of the cutting edge by the amount which it side-cuts the thread form, the contour of the thread above the line A-A in Fig. 4 will be correct and in most cases it will be found that the correction in a straight line will be sufficiently accurate as the resulting error will be negligible.

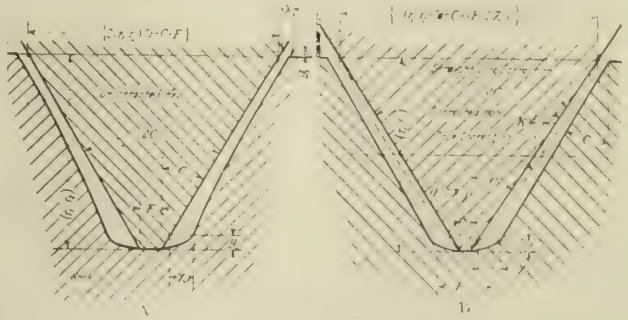

FIG. 5 FORM OF EXTERNAL THREAD CUT WITH UNCORRECTED AND CORRECTED HOB.

Fig. 5-A represents the form of a thread cut with a hob having the form of the cutting edges identical with the true form of the thread. In this figure,

C=half included angle of thread

F=width of flat of thread at the root or minor diam.

$r_1$=largest value of r employed (radius of major diam.)

$r_2$=smallest value of r employed (radius of minor diam.)

$x_1$=maximum minus value of x for $r_1$

$x_2$=maximum minus value of x for $r_2$

$(r_1—r_2)$ = depth of thread

$2(r_1—r_2)$ tan C + F = width of space at major diameter (outside).

Fig. 5-B illustrates a corrected hob and the form of thread cut with it. In this figure,

$F—2x_2$ = width of flat at bottom of hob form

$2(r_2—r_3)$ tan C + $(F—2x_1)$ = thickness of hob form at top.

C′ = half the included angle of corrected hob.

If the cutting edge of the hob is kept as a straight line, the tangent of half the included angle of the hob form will be equal to half the difference between the widths of hob form at the top and bottom divided by the height of the form. Using the values shown in Fig. 5-B, we have the following:

$$\tan C' = \frac{2(r_1—r_2)\tan C+(F—2x_1)—(F—2x_2)}{2(r_1—r_2)}$$

$$\tan C' = \tan C + \frac{F—2x_1—F+2x_2}{2(r_1—r_2)}$$

$$\tan C' = \tan C + \frac{x_2—x_1}{r_1—r_2} \quad \ldots\ldots\ldots\ldots\ldots\ldots (7)$$

It will be seen from Equation [7] and also from the figures that a corrected hob will have a greater included angle than the thread itself; or, in other words, the included angle of a hobbed thread on a screw or male-threaded part will be less than the included angle of the hob.

The dotted line in Fig. 5-B represents the true correction of the hob. Also in this figure,

$r_3$ = value of r at middle of thread flank (or at pitch diameter)

$x_3$ = maximum minus value of x for $r_3$

K = difference at $r_3$ between straight-line correction on hob and true correction.

$$\frac{x_2—x_1}{2} + x_1 = \frac{x_2—x_1+2x_1}{2} = \frac{x_2+x_1}{2}$$

= correction at $r_3$ when hob form remains a straight line.

$$K = \frac{x_1+x_2—x_3}{2} \quad \ldots\ldots\ldots\ldots\ldots\ldots (8)$$

If the rounding or fillet at the bottom of the thread as shown in Fig. 5-B is objectionable, the point of the hob may be extended by an amount about equal to $y_2$, provided that such an undercut is permissible. By so doing an almost theoretically perfect thread form will be secured. Theoretically, the point should extend slightly more than $y_2$ as at this point r becomes smaller and R becomes larger than the values of $r_1$ and $R_1$. Referring to Equation [3], this increase in the value of R will increase the value of r′. Referring to Equation [1], this increase in the value of r′ and the decrease in the value of r will increase the value of y. But for all practical purposes an extension on the point of the hob of the nearest even dimension to $y_2$ will usually be sufficiently accurate. On standard threads cut with hobs the resulting error will be in fifth or sixth decimal place.

For the purpose of simplifying calculations tables have been developed which are given in the complete paper. These tables are based on work whose radius is 1.000. The value of B/360 is given opposite varying values of B and values of y/r are given for different values of r/R. In order to use the tables the value of r/R must first be determined, then the value of y/r is multiplied by the radius of the work to obtain the value of y. The values of y/r may be obtained by interpolation when the value of r/R does not agree with any of those given. The values given under B/360 are divided by N and substituted in the equation x = y × tan C—(B/360N) to obtain the value of x.

In order to illustrate the use of these tables and to determine the effect of carrying the diameter of the hob, values are given in the complete paper for an Acme thread (5 threads per inch, one inch in outside diameter) cut with three hobs, the first one inch in diameter, the second two inches in diameter, and the third four inches in diameter. An Acme thread is selected because the smaller included angle of thread results in more side-cutting, thus making more pronounced the effect of varying the diameter of the hob. The depth of an Acme thread of this pitch is 0.110 in. The included angle is 29 deg. The width of the flat at the root of the thread is 0.0689 in.

The final value of the included angle, 2C′, is given by Equation [7] is found to be 29° 59′ 26″, and in the particular case chosen the difference between the angle of the hob and angle of the work is 59 min. 26 sec. The correction is therefore made in a straight line. By means of Equation [8] the difference K between this correction and the true correction at the middle of the flank is also determined as 0.000064 in. This is negligible and can safely be ignored. In fact, it is much less than the probable error in the hob.

From the values derived in the complete paper the following tabulation is also made to show the various effects

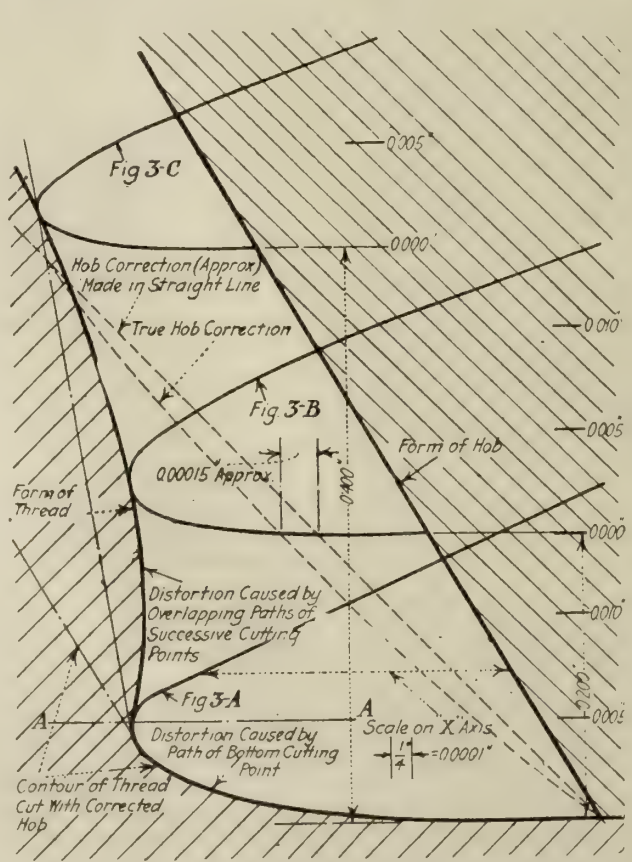

FIG. 1—CURVES SHOWING SHAPE OF CUTTING PATH.

of varying the diameter of the hob. (See Fig. 5-B.):

| | | |
|---|---|---|
| Hob. diam. = | 1.000 in. | 4.000 in. |
| $x_2$ = | 0.002695 | 0.003475 | 0.004048 |
| $y_2$ = | 0.008912 | 0.012344 | 0.014422 |
| 2C′ = | 29° 59′ 26″ | 30° 0′ 16″ | 30° 0′ 54″ |
| F—$2x_2$ = | 0.0635 | 0.0619 | 0.0608 |
| K = | 0.000064 | 0.000054 | 0.000026 |

From this tabulation it will be seen that the amount of side-cutting at the bottom of the thread ($x_2$) increases as the diameter of the hob is increased. The height of the fillet at the bottom of the thread ($y_2$) also increases as the diameter of the hob increases, in fact, it increases about three times as much in this case as $x_2$. The included angle of the corrected hob (2C′) increases very slightly as the diameter of the hob increases. The width of the point of the corrected hob (F—$2x_2$) varies less than 0.003 in. as the diameter of the hob is increased from 1 in. to 4 in. The dimension K in Fig. 5-B is reduced as the diameter of the hob increases.

The correction for angle used in these solutions is a chordal correction. This shows a slight change in angle as the diameter of the hob varies. A geometrical solution of this side-cutting will show that, except for the fillet at the root of the thread, the profile is unchanged regardless of the diameter of the hob. Therefore, if the correction is taken as the tangent of the profile at the pitch line of the thread, the angle C′ will remain unchanged. The formulae for determining this angle are as follows:

Let C = ½ included angle of thread

C′ = ½ included angle of corrected hob

H = helix angle of thread at pitch line

Then

$$\tan H = \frac{1}{\text{pi } N \times \text{pitch diam. of thread}}$$

and

$$\tan^2 C' = \tan^2 C + \tan^2 H$$

It is evident from the above that if the form of the cutting edge of a hob of a certain diameter be corrected to cut a thread of a certain diameter and pitch, a variation in the diameter of the hob of, say, 25 per cent. will have but little effect on the form of the thread produced on the work.

In order to determine the effect of varying the diameter of the work, the following tabulation was made for a hob 2.000 in. in diameter with 5 Acme threads per inch:

| | | | |
|---|---|---|---|
| Work diam. = | 1.000 in. | 2.000 in. | 4.000 in. |
| $x_2$ = | 0.003475 | 0.001161 | 0.000350 |
| $y_2$ = | 0.012344 | 0.004103 | 0.001512 |
| 2C′ = | 30° 0′ 16″ | 29° 14′ 8″ | 29° 3′ 6″ |
| F—$2x_2$ = | 0.0619 | 0.0666 | 0.0682 |
| K = | 0.000054 | 0.000012 | 0.000003 |

The above tabulation shows that the amount of side-cutting at the bottom of the thread ($x_2$) decreases as the diameter of the work increases. The height of the fillet at the bottom of the thread ($y_2$) decreases as the diameter of the work increases. In this case it decreases about four times as much as $x_2$. The included angle of the corrected hob decreases quite rapidly as the diameter of the work increases. The width of the point of the corrected hob increases about 0.006 in. as the diameter of the work is increased from 1 in. to 4 in. The dimension K in Fig. 5-B decreases as the diameter of the work increases. In this case the amount of error introduced by a straight-line correction in the hob is in the fifth and sixth decimal place and is negligible. It is evident, therefore, that a hob which is corrected for a certain diameter of work cannot be used on work which varies very much in diameter if accurate results are desired. The smaller the diameter of the work, the more this condition is accentuated. This is due in large measure to the rapid increase of the helix angle on smaller diameters. On work of large diameters, where the helix angle employed is very small, little or no correction is required on the hob.

## FIRMS THAT ARE ASKING FOR TRADE OPENINGS WITH CANADA

By communicating with this paper and mentioning key numbers, information can be obtained by firms interested in the following lines:

2684.—Wire from nickel chrome alloys. —A firm in Birmingham, England, desire to import from Canada special wire manufactured from nickel chrome alloys.

2686.—Radial Brick.—A firm in Boston, U.S.A., desires to be placed in communication with manufacturers of radial brick for use in building chimneys of power plants and similar structures.

2687.—An important French firm would like to trade with Canada, being specially well placed to export Mediterranean products, and in exchange would like to import wood pulp, acetic acid, mica and asbestos.

2689.—Vancouver concern having representation in Mexico, Japan, China, India, East Indies, Australia, and other countries bordering Pacific Ocean are anxious to get in touch with Canadian manufacturers wishing to extend their operations in that field. Particularly interested in iron and steel, wire, wire nails, nuts and bolts.

## BUSINESS IN OLD COUNTRY STEEL TRADE

### Cutting Prices in Effort to Stimulate Business—Trade Is Not Brisk

In South Wales business continues quiet, but with the lower prices now prevailing it is anticipated that there will be a revival in the demand for steel, and this prospect is confirmed by the fact that a large furnace at Dowlais which has been out of blast for some time has been recently relighted. New furnaces have recently been brought into operation at Ebbw Vale and Blaenavon for the production of billets, etc., but in the latter case the steel departments are short of orders, and the depression in the tinplate trade is exercising a detrimental effect in the output of steel bars, prices of which have been twice reduced during the past few weeks. Until a month ago the official minimum was £21 10s.; this was later reduced to £18 10s., and followed by a further concession of £1 at the beginning of December. Even this price is being cut by non-associated makers, who are offering at £16. Welsh hematite is nominal at £13 to £13 10s., and steel rails have been done at £23.

### Conditions at Sheffield

The steel-producing capacity of Sheffield has been greatly reduced on account of the depression, the open-hearth plant, vastly extended during the war, proving productive in excess of the present volume of demand. The trade in high-speed steel is also in a low state. As regards steel and manufactured goods, manufacturers have been disappointed by some heavy cancellations. The only departments which are fairly active are those producing railway steel, steel castings, tools for building and general trades, and agricultural tools.

Soon after the end of the boom prices of materials began to fall, and although the movement has been slow and has scarcely affected the best qualities of steel, it has made possible substantial reductions in the selling prices of finished goods produced from the cheaper steels. Iron has fairly held its own, but has now begun to fall. The output of wrought iron is so small, however, that makers can command their own terms.

The Imperial Oil Co., Ltd., are planning to erect a two-story, fireproof office, a large two-story fireproof garage, a boiler and pump house and a plant for the repair and care of barrels, at Brandon, Man. Two ten-thousand barrel tanks will also be installed and the necessary lubricating storage plants. It is expected construction will begin in the spring and be completed in the fall of 1921.

# Effect of Relative Humidity on Leather Belts

## Explanation of Humidity, Relative Humidity, Testing Apparatus, Atmospheric Control, Standard Conditions and Series of Tests

*By F. W. ROYS, M.E., Worcester Polytechnic Institute

ANY ONE who has ever had anything to do with leather belting knows that an ordinary oak tanned leather belt, not waterproofed or weather proofed, changes its characteristics considerably with the weather conditions, and it was because no information was available regarding these effects that the experiments were undertaken.

All of the experiments were made on a single specimen of belting, and it will not be contended that the results are applicable, directly, to any other belt. However, it is assumed that if consistent results have been obtained for this particular sample, other belts of the same sort of material will show similar characteristics, the same in kind, if not in amount.

Any work done in any branch of belt testing may easily run on interminably because there are so many variables that must be considered. It is therefore necessary to fix as many conditions as possible, and to accurately know all the others at any stage of the test.

In this particular investigation the following method was finally adopted:

1st. An oak tanned leather belt was selected. This belt was a 4" single belt about 25 feet long, first quality; 2nd. The belt was made endless and operated over a pair of 24-inch diameter, 6-inch crown face cast iron pulleys; 3rd. The belt speed was maintained as nearly constant as practicable at about 1,900 feet per minute; 4th. The transmitted horse power was kept constant; 5th. The temperature was kept constant except in the last part of the work when the sum of the belt tensions was kept constant instead.

*A paper read before the National Association of Leather Belting Manufacturers.

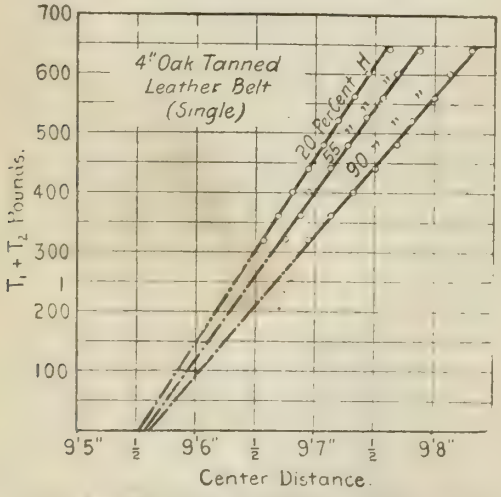

FIG. 2—RELATION BETWEEN T1—T2 AND CENTER DISTANCE AT THREE CONDITIONS OF RELATIVE HUMIDITY. HORSE POWER CONSTANT.

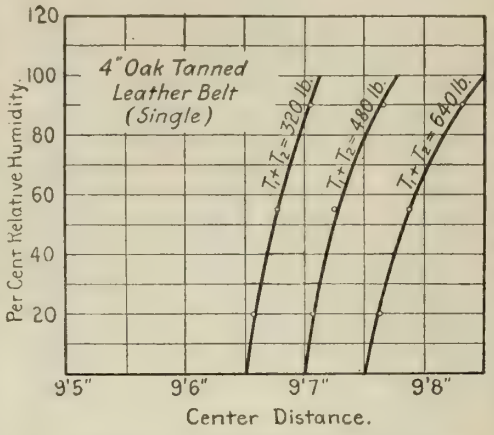

FIG. 3—RELATION BETWEEN PER CENT. RELATIVE HUMIDITY AND CENTER DISTANCE AT THREE CONDITIONS OF T1+T2. HORSE POWER CONSTANT.

Having fixed the above conditions it was considered that three important ones were left to vary. They are: 1st, the belt length; 2nd, the sum of the tensions in the tight and slack sides of the belt; 3rd, the relative humidity.

### Explanation of Humidity

The condition of the atmosphere which has to do with the moisture content is called humidity. The actual weight of water vapor held in a cubic unit of the atmosphere is understood as the absolute humidity, and this amount of moisture varies greatly with the temperature.

The ratio between the amount of water vapor actually in the atmosphere at any temperature compared to the maximum amount which it would carry at that temperature is known as the relative humidity. Either one of these ways of considering the humidity might have been used, but it seemed more natural to use relative humidity for this work and it is felt that it will be of more benefit to most people to consider the effects from that standpoint.

### Measurement of the Different Variables

**Belt Length.** Instead of measuring the belt length directly the distance between the shaft centers was measured as being a direct function of the belt length.

**Some of the tensions. $T_1+T_2$.** When a belt is working over any pulley, the tension of one side is of course greater than on the other side of the pulley. The tension in the tight side is to be designated as $T_1$ and the tension in the slack side as $T_2$. Then $T_1+T_2$ is the total pull of the belt from both sides of the pulley (see blackboard sketch). The sum of the tensions was easily measured by means of platform scales bearing the foot of a bell-crank lever whose arm was connected by a chain to the carriage of the apparatus. See Fig. 1.

**Relative Humidity.** The relative humidity was determined by a sling psychrometer, similar to the type developed by the U. S. Weather Bureau. The sling psychrometer is a simple instrument made of two mercurial thermometers placed side by side in a frame. The

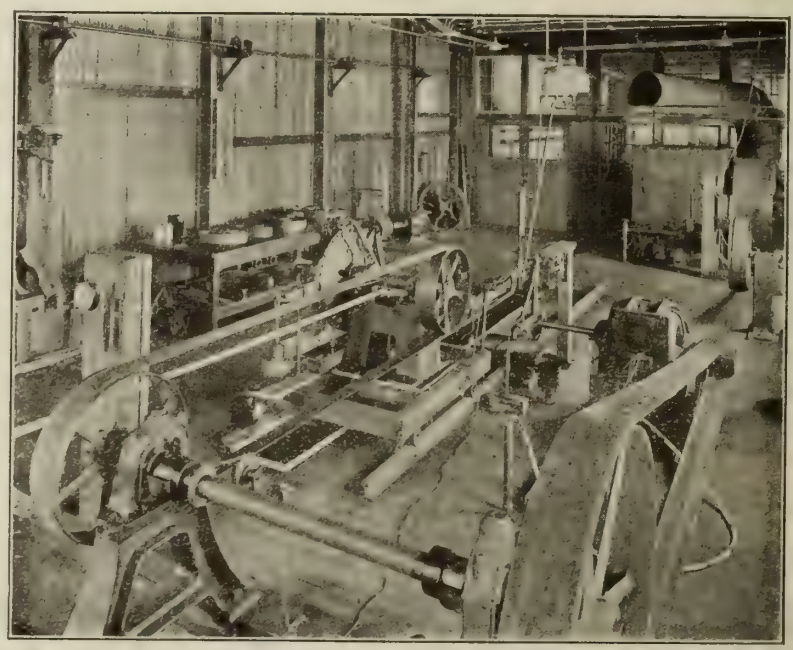

FIG. 1—SHOWING THE APPARATUS USED.

frame is attached at one end to the swivel handle so that it may be whirled, thereby causing the thermometer bulbs to move rapidly through the air. One of the bulbs is covered with a piece of fine muslin and, before the instrument is whirled, this muslin is dipped in water. It thus is a special type of wet and dry bulb thermometer set. The advantage of the type of wet and dry bulb thermometer is that the rate of evaporation is much more definitely controlled than in an ordinary stationary set which has to depend on whatever air currents may be stirring.

A precision hair hygrometer was also used, but could not be depended upon except to indicate whether the humidity was constant or not.

### Method Used in Investigation

In order to study the three variables already referred to above three sets of experiments were carried out as follows: First. Determination of the relation between the center distance and $T_1+T_2$, relative humidity remaining constant. This simply means that the tightness, or looseness as you please, was varied and the corresponding stretch carefully noted, great care being taken to see that the atmospheric conditions did not change.

Second. Determination of the relation between center distance and relative humidity. $T_1+T_2$ remaining constant. Or in other words, the condition of the atmosphere was changed and the corresponding stretch or contraction was noted, care being taken that the sum of the tensions, or $T_1+T_2$ did not vary.

Third. Determination of the relation between relative humidity and the sum of the tensions. Center distance remaining constant. This means that the condition of the atmosphere was varied and the effect on the sum of the tensions was noted, while care was taken to see that the center distance remained always the same.

### Description of the Apparatus

A general layout of the apparatus used in these experiments, which were conducted at the Worcester Polytechnic Institute, is shown in Fig. 1.

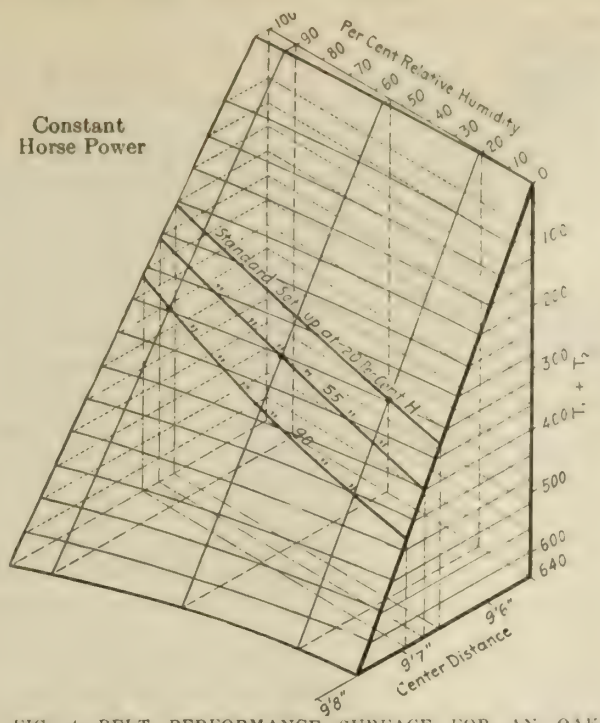

FIG. 4 BELT PERFORMANCE SURFACE FOR AN OAK TANNED LEATHER BELT 4 IN. WIDE, SHOWING RELATION BETWEEN CENTER DISTANCE, SUM OF TENSIONS AND PER CENT. RELATIVE HUMIDITY.

It consists of a driving pulley mounted on a shaft whose bearings are in fixed hangers and a driven pulley mounted on a shaft carried by a base which rests on a movable carriage. If power is to be delivered to the pulley on the movable base two reactions must be furnished. First there must be a direct pull to equal the sum of the belt tensions. This pull is furnished through a chain, equipped with turnbuckles for adjustment, one end of which is fastened to the carriage and the other to the bell-crank lever which has already been mentioned and which serves to measure the amount of the reaction. Second there is the torque or twist. This torque is furnished by an Alden absorption dynamometer, and the amount of the torque is weighed by balancing the dynamometer with standard weights at the end of a definite length of lever arm.

The Alden dynamometer is simply a defined form of Prony brake of large capacity in proportion to its size. A single disc dynamometer consists of a cast iron disc which is keyed to the shaft, and which rotates in oil between two copper plates which are fastened to the casing. Water under pressure is admitted to the casing, thereby pressing the coppers toward the cast iron disc and making the oil film thinner. The more viscous the oil and the thinner the oil film the greater the torque required. The casing, not being keyed to the shaft, is restrained from turning and the force, at a definite radius, necessary to restrain it is a factor in determining the power transmitted. The water not only furnishes pressure, but since there is a constant circulation it also serves to take away the heat of friction. An automatic valve serves to regulate the pressure and the regulation is so nice that oftentimes one of these brakes will run for an hour or more if necessary, always in perfect balance.

The load on the dynamometer is a direct function of the difference in tensions or $T_1+T_2$. Since $T_1+T_2$ and $T_1-T_2$ are both easily measured $T_1$ and $T_2$ may each be easily calculated.

### Atmospheric Control

A Sturtevant heater and blower was used to heat and circulate the air. At first it was attempted to control the humidity by a humidifier such as is used in cotton mills, but finally a live steam

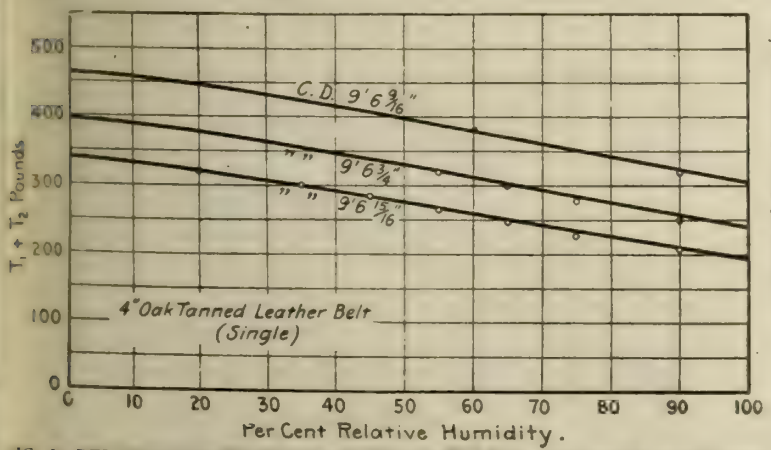

FIG. 5 RELATION BETWEEN T1 + T2 AND PER CENT. RELATIVE HUMIDITY FOR THREE CONDITIONS OF CENTER DISTANCE HORSE POWER CONSTANT.

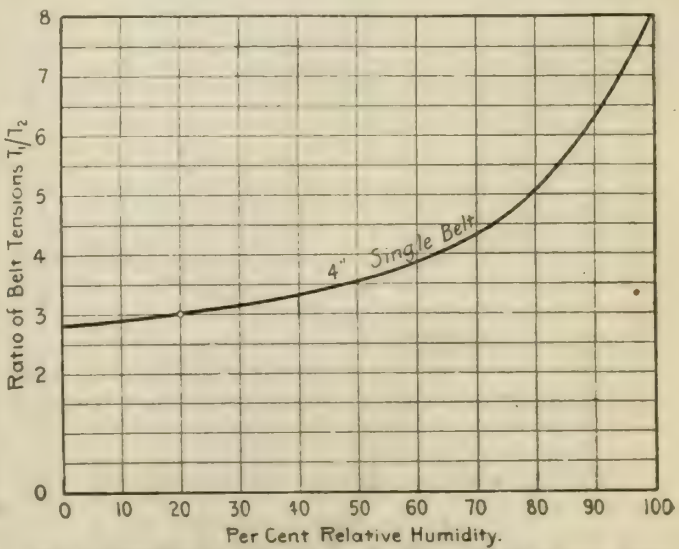

FIG. 6 EFFECT OF CHANGE OF HUMIDITY FROM 20 PER CENT. HORSE POWER CONSTANT.

jet was used altogether. It was found that the humidifier made just a fog, that is minute globules of water suspended in the air, and not vapor containing the heat of vaporization. It was found that no consistent results could be obtained when using the humidifier, but that perfect consistent results which could be duplicated at any time were obtained by the second method.

### Standard Conditions

Certain ideal conditions were assumed as a standard. These were as follows:—Tension in the tight side of the belt $T_1$ = 240 lbs. or 60 lbs. per inch of width. Ratio of the tension in the tight side to the tension in the slack side 3 to 1.

Now if $T_1 = 240$ and $T_1/T_2 = 3$ and we wish to know the tension $T_2$ we have

$$\frac{240}{T_2} = 3$$

Or $3T_2 = 240$

and $T_2 = 80$

Then $T_1 - T_2 = 240 - 80 = 160$ lbs.

This difference in the belt tensions multiplied by the radius of the pulley, in fact, is the number of foot-pounds of torque received by the belt. The power transmitted is of course also a function of the speed and in this case the speed was such that the horse power was approximately 9.21. This value for the horse power prevailed throughout the test and since the speed was constant the value of $T_1 - T_2$ remained constant regardless of what either $T_1$ or $T_2$ may have been.

For the specimen belt which was used and for the conditions stated above, the creep was between 0.8 and 0.9%.

### First Series of Tests

The first series of tests was made by changing the sum of the tensions and measuring the centre distance (belt length) for three different values of relative humidity. The three values of the relative humidity were 20%, 55%, and 90%.

Fig. 2 shows the results of this test graphically and the significance of it is that the modulus of elasticity of the belt, or the ratio between the load applied and the stretch produced, is different for different values of the relative humidity. It is readily seen from the diagram that

given change in tension at a high humidity than at a low.

### Second Series of Tests

The second series of tests, that is the series with $T_1 + T_2$ constant, was carried out with three different values of $T_1 + T_2$. Fig. 3 shows these results graphically and it shows quite clearly that the stretch of a belt for a given change in

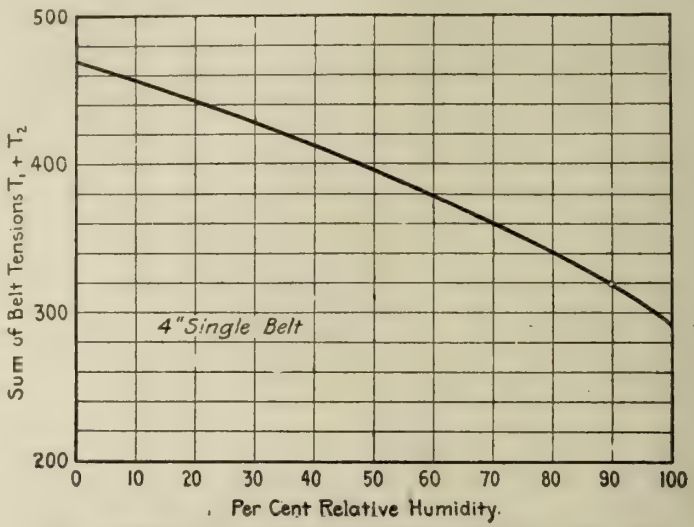

FIG. 7—EFFECT OF CHANGE OF HUMIDITY FROM 90 PER CENT. HORSE POWER CONSTANT.

humidity is greater at high tensions than at low. It would be strange if this were not the case but this test showed just what the variation was.

From these two sets of data which are in terms of three variables it is possible to construct a diagram in space and the result is a surface such as is shown by the diagonal face of Fig. 4. Any one of the curves already referred to may be located on this surface. It is only necessary to know what condition was constant and also the value of that constant and then to trace the curve in terms of the other two coordinates.

The data for the construction of Fig. 5 was obtained in this manner and the curves were drawn. Afterward the belt was operated at different values of relative humidity and the value of $T_1/T_2$ was noted. The plotted points are the results of the experiments and the fact that they lie so close to the calculated position is All of the factors being more or less unknown it is impossible to make definite predictions regarding other leather belts.

However in a general way it may be stated that the effect of a change in the relative humidity is greater at high humidities than at low; that the effect is shown more rapidly in single than in double belts; that increasing the humidity shows practically immediate results, while a decrease in the humidity takes a longer time to be effective.

Much more attention should be paid to the effect of the relative humidity than is ordinarily the case. This will be apparent from the discussion that follows.

Suppose that a plant has an engineer who is supposed to see to it that belts are kept tight and working at the proper tensions. Suppose also that he pays no attention to the weather conditions, but has the belt tightened to a tension which he calls standard.

Continued on page 99

### Conclusions

The warped surface shown in Fig. 4 might well be called the characteristic of this belt and it indicates in a general way what might be expected from similar belts. Leather itself will vary due to various causes as you are well aware.

good evidence that there was no error of any account in the other work.

# Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

## What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

Here are the two prize-winners for the January 13th contest. Daniel Sheg, 559B Berri St., Montreal, and George Land, 567 Patterson St., Peterboro', Ont. One of our contestants asked this question, "Can any reader of Canadian Machinery try this contest, even though he is not a subscriber." Certainly, the more answers we receive, the better we are pleased, although we cannot imagine anyone reading Canadian Machinery and still remaining a non-subscriber.— Editor.

**CONTEST FOR FEBRUARY 3RD ISSUE**

**Contestants are required to write us, stating to which advertisements we refer in this number.**

1—Something that lifts 200 times its own weight.
2—Something that is like a cannibal—eats them up.
3—A product said to be of dependable character.
4—What to do if you have work requiring accuracy.
5—How to increase production.
6—How to become a candidate for a steady job holding a tin cup.
7—Something said to be equally efficient for light or heavy work.
8—How to save many valuable hours.
9—Something that will stand up to its work.
10—Something that has served five years' service and is still a favorite.
11—How to make sure of good gears.
12—How to save money on cost, also delay in deliveries.

**These are Correct Answers for List from January 13th Issue:**

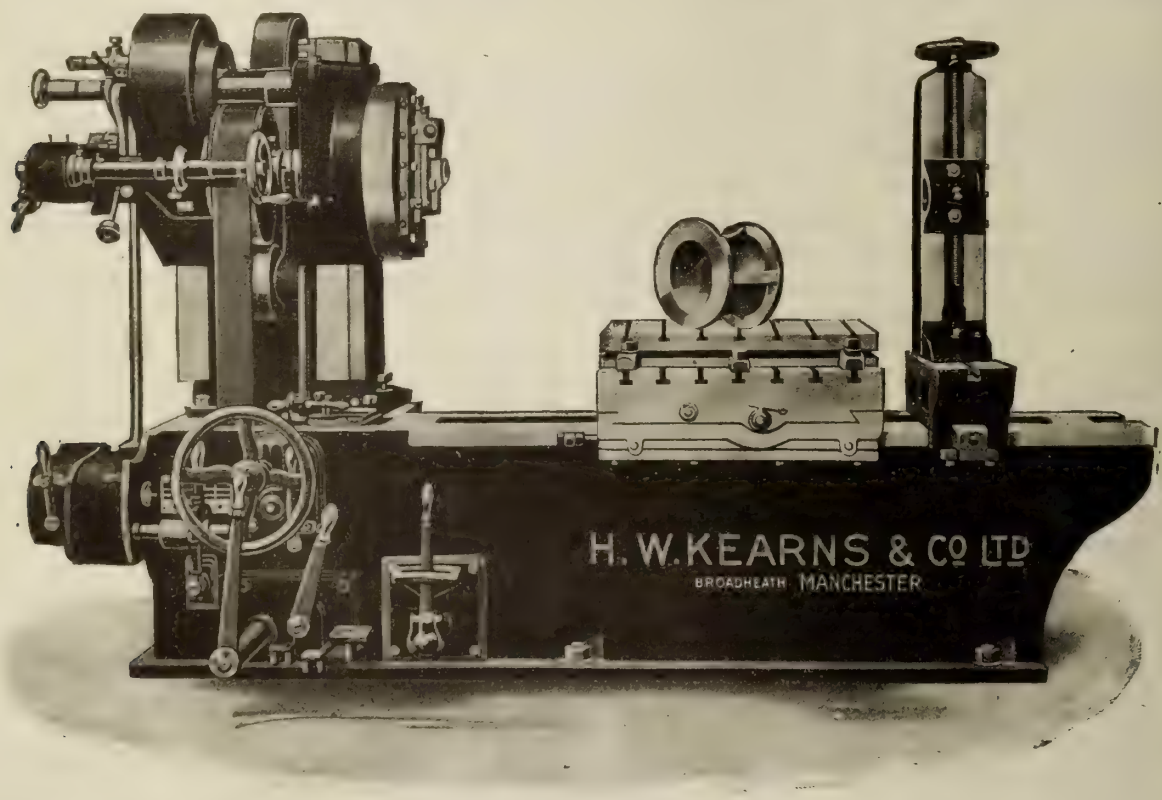
1—Dominion Oxygen Co., Ltd.
2—Bristol Co.
3—H. H. Robertson Co.
4—J. H. Williams & Co.
5—Wright Mfg. Co.
6—Holden Co.
7—Nicholson File Co.
8—Victor Tool Co.
9—Landis Tool Co.
10—Wilt Twist Drill Co.
11—J. T. Hepburn.
12—In the Classified Section, or Buyers' Directory of Canadian Machinery.

## Closing Date for This Contest is February 24th

# DEVELOPMENTS IN SHOP EQUIPMENT

### MACHINE WITH MANY USES

You can accomplish surfacing, boring, milling, drilling and tapping on the one machine. Briefly, that is what H. W. Kearns & Co. Ltd., Broadheath, England, claim for their patented multi-purpose machine shown in Figs. 1 to 3 inclusive. These machines are made in two types, known as the standard and the patent machine. In all essential features they are similar, and with the exception of certain parts are identical and interchangeable. The standard machines are fully universal, and are capable of handling a very large variety of work.



They are said to be especially suited for marine work, pump work, and in fact any work of large size, and where the operations take considerable time, also where the diameters dealt with are well up to the capacity of the machine. All boring feeds are obtained by travelling the tables, and this is the method they recommend for holes of large diameter, as it allows them to use good substantial bars.

This concern have proved by experience that a demand exists for a machine similar to the above, but with the addition of a travelling spindle, so the patent machine, next to be described, was produced. This latter machine contains all the features of the former with the addition of a travelling spindle of substantial diameter. The advantages of such an addition for certain classes of work are easily understood. Where the operations are great in number, and the holes to be bored are of small or medium diameter, it is much more convenient to travel the spindle. The patent machines are supplied with a larger table than the standard type. This is due to the fact that there is a tendency to require less space between the boring bar socket and stay on this type of machine, owing to the reduced need to travel the tables where a travelling spindle is available. The travelling spindle can be revolved either simultaneously with, or independently of, the facing chuck. This is a feature of considerable importance, as the independent action of the spindle will be found of benefit for drilling, tapping, and boring of small diameters. In addition to these features the momentum of the facing chuck when running at high speeds is avoided. Where cylindrical articles are manufactured in large quantities, the patent machine will bore and face simultaneously.

At Fig. 1 is shown a general view of what is known as the No. II standard machine, while at Fig. 2 is illustrated the facing slide for the standard type of machine. Fig. 3 depicts the type of facing slide for the patent machine, and it will be noted in this latter case that a clear hole is left through the spindle of the clutch to carry the travelling spindle.

### Facing Slides

The facing slides on these machines are patented and embody certain features. For example, they are capable of facing from the maximum diameter to zero without adjustment. This overcomes the usual trouble of changing the

GENERAL APPEARANCE OF THE NO. II. STANDARD MACHINE.

position of nut before the job can be completed. Before adopting the present patented facing head they had this trouble to contend with, and the adoption of this type of head has saved considerable time. Their patent clutch consists of a section of a worm, operated on a helical rack carried on the back of the facing slide. Ball thrusts are provided in each direction, and in addition to the advantage already mentioned, increased bearing surface and reduction of effort required for hand adjustment are obtained. The facing tool is arranged to make an acute angle with the work, thus reducing the chance of chatter. This principle is found of special value when finishing work at a broad rate of travel. The slide is fitted with detachable socket for carrying boring bars, twist drills, reamers, snout boring tools and milling cutters. Special adjusting strips are provided which ensure the slide remaining in truth when in central positon.

In the patent machine head (see Fig. 3) it will be noticed that a radial motion is given to the facing clutch by means of a scroll plate carried at the back of the facing slide. The engaging portion of this plate is of large diameter, and it makes engagement with two scroll sections spaced sufficiently widely apart to admit between them the travelling spindle. Automatic feed is obtained in either direction by accelerating or retarding the scroll plate relative to the facing slide. This feed is obtained from the main feed box operating through an epicycle gear. By this means a wide range of feeds is obtained. The facing head is provided with tee slots running its full length. The tool holder can thus be placed in the most convenient position, and a boring bar is supplied which is secured to the facing slide for use when it is desirable to use fixed bars of large diameters in conjunction with the table feed.

### Spindle Slides

The vertical sliding head is geared to enable the machine to deal with work varying from the largest to the smallest diameter, and power is transmitted to the spindle by means of an endless belt. When drilling or boring small diameters this driving pulley is directly connected to the spindle, thus obtaining direct drive without the intervention of toothed gearing. In holes of large diameter the power is transmitted from the belt to the spindle through gearing of ample purchase, operating on an external pinion, driving through spur ring of large diameter. The spindle is relieved of all torsional stress when boring large diameters. All bearings are of ample proportion, and are kept as far apart as possible, thus allowing the use of snout boring tools.

The spindle slide on the patent machine is identical with the one already explained, and the travelling spindle is carried on bearings of ample length. Automatic feed to the spindle is provided in either direction, together with reverse motion for tapping. The spindle is gripped in a tail bracket, and is sufficiently long to give twice the travel provided with instantaneous engagement for automatic feed. A fine hand adjustment is also provided.

The feed motion to facing slide is of patented improved design, and these feeds are now taken from the main feed box. This is connected to the facing slide through epicycle gearing, with the result that as many feeds are provided to the facing slide in either direction as are provided to the other motions of the machine. In other words eight feeds in either direction are provided to the facing slides on the standard machines.

### The Tables

The machine is provided with a rectangular main table arranged with adequate cross traverse. On the main table is fitted a detachable square turntable which enables the machine to operate on all four sides of the work at one setting. The table can be locked in any position, and at any angle. It is fitted with a special patented locating arrangement which locks it securely at each 90 degrees.

Tee slots are provided on both tables. A centering pin is used whereby the detachable turntable is located central with the spindle. A spacing arrangement is also provided when required that enables the proceeding of repeat articles with perfect uniformity.

### Rapid Power Traverse

The machine is fully automatic, variable and reversible feeds being provided to the longitudinal and transverse motions of the table, and to the vertical motion of the sliding head. This renders the machine capable of milling in all directions. Rapid power traverse is provided to the whole of these motions in either direction. This traverse is independent of the feeds, and is of constant speed.

Alfred Herbert, Ltd., are handling these machines for the Canadian trade, from their offices at 1-3 Jarvis St., Toronto.

## Asking—And Getting It

AT a meeting of the Canadian Association of British Manufacturers held in Toronto a few days ago, several remarks were made by representatives from various fields and the trend of these could be interpreted as meaning that conditions were mending. One dealer put the thing tersely when he said: "We are asking for business now and we are getting it."

The casualty list in Canadian industry has been light and the same holds good in other fields.

Dealers in other lines, such as foodstuffs, are protecting their customers for a reasonable length of time on prices. That is, they promise stability of prices for a period that will allow the dealer to dispose of a reasonable amount of goods. It is encouraging buying on a larger scale and the movement is growing.

## The Market Not Crowded

IN a signed statement by T. A. Russell, president of the Willys-Overland Co., the much-repeated talk of overstocked automobile dealers is plainly denied. The remark has often been made that as soon as prices were cut some months ago dealers rushed in and bought very large stocks for the 1921 trade and therefore put an end to the buying movement as far as they were concerned for some time to come. Mr. Russell's statement follows:

"Motor dealers in Canada can look forward to 1921 with confidence. The statistics which were prepared by the manufacturers and dealers for submission to the Government in connection with the question of luxury taxes, brought out the surprising fact that the total number of cars in the hands of dealers, throughout the whole of Canada, did not exceed the normal production of the Canadian factories for one month. In other words, one month of normal sales would dispose of a greater number of cars than were in stock in the hands of dealers in Canada on January 1, 1921."

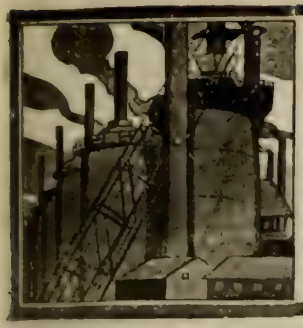
Dealing with general conditions, all of which will have a very direct bearing on the sale of cars and other business, Mr. Russell goes on to say: "A large part of Canada's grain crop has not been moved. Canadian banks and institutions have stood the strain of reconstruction without an important casualty. Liquidation, which has been so general, has been accomplished without shaking our commercial credit. Are these conditions not a sound basis for a healthy and profitable business in 1921?"

## Making Salesmen Now

THERE are certain business houses where the visitor knows what to expect now. Go in and make a call. Sit down and talk for a few minutes. You will come out with an ear full of gloom. You will hear that the firm is not making money; that they are not selling as much as they did last year; that the future is uncertain.

After one gets well sprayed with that kind of speech it is easy to pass a little of it along.

Thank goodness there are other places. This week we found one that was out for a record year. Yes—not an inch less—out for a record year.



Their motto may be rather straight and unadorned, but it means this—the way to get business is to get it.

"We are going after business now in a way that some of our new salesmen never heard of before. There has not been much selling done since 1915—largely a case of taking orders. It's bad for the whole force. Salesmen are developed when business is not brisk, when the traveler has to think, has to study the business of his client, has to find out if he has anything to sell him that he should have. We believe there will be more salesmen developed in Canada during the year 1921 than there have in the previous five years."

# MARKET DEVELOPMENTS

## Inquiries Are Numerous, But Not The Orders

### Pittsburgh Despatch Intimates That New Basis For Steel Values May Be Reached—A Few Reductions Made in the Price of Tools—Scrap Metal Prices are Marked Down in This District To Very Low Levels.

PRICE talk is heard again in the markets this week, but this does not mean that there is going to be any immediate advantage in it for the Canadian buyer. New York reports that two makers have brought out new selling schedules, but there is nothing to show that the action has aided in the closing of any more business. Pittsburgh also talks about a new basis for steel prices, but intimates that the time is not ripe yet for the bringing of these into effect. Wages and other costs will have to be dealt with first, and there is a feeling that cuts in wages would lead the buying public to turn on the steel makers and ask them for cheaper steel.

Machine tool dealers in Canada are working harder for business than for some time past and the experience of many is that the firms that are working hardest to secure business are meeting with the most gratifying results. The change in the attitude of some American firms in opening a Canadian account and taking payment in Canadian funds has also helped sales.

Buying that is being done, though, is on a small scale, although reports indicate that industry in Canada is improving. Some shops are releasing orders they have held up for some months and more are getting under way even if on a small scale.

The scrap metal market was further marked down this week, many of the figures now named being only shadows of their former war-time greatness. Even at this schedule there is little trading being done.

## SOME LARGE SHOPS IN MONTREAL ARE FARMING THEIR WORK OUT

Special to CANADIAN MACHINERY.

MONTREAL, Feb. 3.—The past week has brought nothing new to the surface. Some reports indicate that business is more brisk, while on the other hand one hears of the suspension of operations at some of the larger plants, with many willing, but not knowing how, to help put trading on a firmer basis. When speaking to the proprietor of a small machine shop here he made the remark that: "We have succeeded in obtaining sufficient work to keep us going for several months, and with the promise of more. The peculiar fact, however, is that this work has been obtained from one of the largest firms in the city, as it appears that they have let nearly all of the tool makers go, and when it is necessary to have such work done they are sending it out to the small shops. It is my belief that the small shops will be the first to benefit from the situation now confronting us, as the larger shops will prefer to have work sent out rather than take on more men just now, or until there is a general return to normal activity."

### Steel Remains Quiet

"We are still looking forward to the time when business will be more than the answering of inquiries. If orders resulted from all of these we would have no cause for worry, but in the great majority of cases it seems as though they were feelers to get the trend of the market." This statement by a steel dealer would indicate that buying is contemplated, but that their needs are not sufficiently urgent to place an order, except it be for material wanted for immediate use. There is a tendency on the part of sales organizations to offer inducements to buyers to fill their requirements, but these are not shown on the price quotations, the latter being maintained for moral influence. The feature that dominates present trading is the lack of interest shown by the average consumer, and this attitude makes it all the harder for the salesman when trying to secure an order. "We cannot complain of present business," said one dealer, "as we do not expect any heavy buying at this season of the year. We are keeping just sufficient stock to satisfy the spasmodic demand of the trade. January and February are usually quiet in normal times, so we are showing no anxiety. Should our expectations be realized we will in a few months require to carry more in our warehouse to meet the summer needs of the trade." Local quotations are firmly held in many cases. Sheets are easing off somewhat, and that in face of the gradual return of automobile activity.

No visible improvement has, as yet, developed in machine tool movement, although a few dealers state that the past week has brought out several interesting inquiries. Not all of these have resulted in sales but the encouraging tone has given heart to those who have frequently despaired of an early return to active business. "We cannot say that present business is much improved over that of the past few weeks," remarked a dealer here, "but when you realize that the past three or four months have produced little more than sufficient to pay overhead, the possibility of increased business is an encouraging feature in an otherwise quiet period. We are not anticipating any rapid return of normal activity but everything points to a steady betterment in business generally, a condition that will naturally be shared by those in the machine tool lines. Prices—this is a question not easily settled. Of course, some makers endeavor to meet the desires of the trade in this respect, but new tools continue to find their way to the users at figures in keeping with general conditions, and these require that a fairly high standard be maintained."

Those houses that make a practice of catering to the rural districts have been fortunate in securing some business but usually small and well distributed orders. Even this, however, is very acceptable. There is still a fair movement in small supplies but volume is light, salesmen endeavoring to maintain sales by extending their calls and covering more territory.

# CANADIAN FUNDS MADE THE SALE

**Feeling Grows That Firms That Get Out After Business Will Secure Orders**

TORONTO.—One has not to make many calls in the Toronto market at present to pick up any shade or variety of opinion, but through them all there is a note that the worst has happened, and events are certain to turn for the better soon. Even in cases where they admit that it is a case of nearly all going out with very little coming in, they look forward to a good year's business, and look upon the present in the light of the whole year.

"We are going to have a good year," was the statement of one firm this morning. "We are going to have a good year because we are going after the business in a different way. Our men are out now to sell, and not simply to take orders. It's not a good thing to have business coming too easy. It is a great chance right now for salesmen to show that they know something about the fine points of the game. It has been no trick for some years past to make a showing like a fairly good machine tool salesman, but for the past six months or so this has changed. The man who can get away now and pick business out of this market is the man we want around here. It's a great chance for men out selling to do some real constructive work now. We are finding out that the man who gets out now and fights for business is getting the results."

Machine tool dealers report nothing from their principals that would indicate any intention on their part to let down the prices. In fact the matter is not discussed in the markets now nearly as much as it was a few weeks ago. It seems to be generally conceded that there will be price changes some time later on, but it cannot be said that this consideration is making much difference. There are other factors, amounting to about the same thing, though, that do result in sales, and it is worth noting that other cases might work out the same way.

### Here is the Case

A Canadian firm had secured a figure from a Toronto house on a certain kind of drill for a special purpose. The first quotation was made last May, but the deal was not closed, and apparently the would-be purchaser had let the matter drop. He called up on the phone the first of this week, and asked what the price was at the present time. He was informed that there had been no change in the price, but that the firm would now accept Canadian funds at par, a change which had been made in their selling policy since the quotation in May. "If that's the case, send along the machine," was the answer.

## POINTS IN WEEK'S MARKETING NOTES

**Pittsburgh states that the price of steel may come to a lower level, but the present is not an opportune time to bring about this change. Wages and other costs will have to come down first.**

—

**Steel Corporation mills are continuing to operate within 10 to 12 per cent. of their capacity on orders booked some time ago. There is not much new business being placed.**

—

**Some of the larger shops are farming out portions of their work rather than start their whole plant operating.**

—

**The prices that dealers were paying for scrap metal were cut again this week. Any sales that are taking place now will bear an intrinsic value to the market.**

—

**The steel companies have enough scrap to last them for months to come, and foundries are buying only what they need.**

—

**One maker of grinding machines and another manufacturer of shapers have announced reductions in their selling prices, but other machine tool makers have not followed suit.**

### Steel Market Quiet

Steel prices have not changed during the week, nor are there indications that there will be anything much of a departure from present lists for some time. There are offers made to Canadian dealers now to take on tonnages from American rolling mills that are out looking for business, but the average yard in Canada has all the material it cares to handle now, and for the most part they much prefer to clean out their stock, even without profit, rather than add to it at fairly close prices.

There is a certain amount of buying being done, but it is not in a large way.

### More Prices Are Cut

The prices which dealers will pay for scrap material were operated on again this week, and now they possess only a very small share of their former war-time greatness. In fact were the dealer to take his club and whack the schedule any lower it would simply cease to exist.

Speaking of the changes, one of the dealers said "Foundries are not taking on anything to speak of, neither are the steel companies. The latter are pretty well loaded. If some of them keep on producing at their present low rates they will not have to buy anything for the next year or so. The large dealers are not taking on anything. They are pretty well stocked, and are afraid of even lower prices. They have been taking their losses pretty regularly for some time now. Anything that is bought or sold at present prices is below the intrinsic value of the material, but that seems to make no difference."

One might imagine it would be a good time for the speculators to get busy in the metal market, but they are afraid of it. When copper came down recently and hit 14 cents for the first time in many months, there were several in this district quite eager to go in and take a chance. They did, and all that is necessary is to say that to-day copper can be bought in New York at between 12 and 13 cents.

# NEW YORK MARKET STILL MINUS ORDERS

**Some Changes Have Been Made in Selling Prices, but They Are Not General**

Special to CANADIAN MACHINERY.

NEW YORK, Feb. 3.—There is as yet no marked improvement in the demand for machine tools, though a fair number of inquiries for single machines is being received. Orders are few, however, and buyers are evidently awaiting the working out of the price situation.

The most important reduction of the past week was that of the Norton Company, Worcester, Mass., which made varying changes in its prices on grinding machines and grinding wheels. These declines approximated 15 per cent. Other wheel manufacturers have also reduced, but the reduction in grinding machines is not general. Some of the Norton Company's competitors on tools have not indicated whether they will or will not make like reductions.

Manufacturers of shapers have likewise not followed the action of Gould & Eberhardt in reducing prices about 15 per cent.

Prices on riveting machines made in New England have been reduced 12½ per cent. Nearly all of the makers of precision bench lathes have reduced prices.

A large manufacturer of foundry equipment announces a second reduction of prices within one month, making a 20 per cent. cut in all.

Some of the machine tool manufacturers intimate that they will make no reductions at present. The general disposition toward the price question is that reductions at this time will not stimulate buying.

During the past week or two there has been a slight improvement in business among some of the metal-working industries. The improvement is in evidence mostly in the smaller shops.

Many of the large plants are wholly or partially shut down. The General Electric Company has just announced a reduction in wages and has also cut down the size of its office forces. This is typical of the situation as it exists among many metal-working plants.

It is the general opinion that a slow but gradual improvement in the business situation may be expected from now on. Few, however, are willing to predict that there will be any real activity in some of the metal-working lines before the last half of the year.

# STEEL PRICES MAY SHIFT AGAIN BUT TIME FOR IT IS NOT RIPE

Special to CANADIAN MACHINERY.

PITTSBURGH, February 3. — There has been a slight increase in production by independent steel mills as a whole, the average rate of output by independents now being in the neighborhood of 30 per cent., against a 25 per cent. average for several weeks. The increase in production, however, does not seem to reflect any definite increase in demand, but seems due rather to several mills chancing to resume work at the same time, after a spell of idleness in which they allowed orders and "releases" to accumulate, the releases being withdrawals of instructions previously issued to discontinue shipments on old orders. At some time in the future several mills may chance to go down entirely at the same time, and then a particularly low operating rate will be shown.

The Steel Corporation is operating at an average of about 90 per cent., on the basis of the steel ingot production. Operations have decreased slightly of late by the American Steel & Wire Company, Illinois Steel Company (operating also the Gary plant) and the Tennessee Coal, Iron & Railroad Company. The National Tube Company continues to operate full. The Carnegie Steel Company has been maintaining an average output of ingots 96 per cent. of rated capacity, and last week blew in an additional blast furnace, making 48 Carnegie stacks in operation, the largest number for months. The American Sheet & Tin Plate Company, an important subsidiary of the Steel Corporation, but one that makes very little steel, maintains its former rate of operation at its tin plate mills, but has tapered off slightly in sheet mill operations.

There is no certainty that the Steel Corporation will be able to maintain even approximately its present rate of operation for any length of time. The large mass of business the Steel Corporation accumulated on books last year has proved very sound except for a small volume of cancellations, much sounder than the independent steel producers expected would prove to be the case whenever the steel situation should turn easy, but that would not prevent the buyers from requesting that shipments be made at a slower rate. The consumer may be able and anxious to take every ton on his contract, but his rate of operation might be such as to require that deliveries originally intended to be completed by June 30 should be strung out to December 31.

### Prices

There is some price cutting in a number of the finished steel products, but the cutting does not amount to much in either volume or extent. As to volume, the Steel Corporation is probably booking more business than the independents, and of course its prices are absolutely firm, while some at least of the independents are holding strictly to regular prices, yet are booking an order here and there. As to extent, the maximum shading, where there is any at all, is probably only $2 or $3 a ton.

However, this does not indicate that present prices are going to hold. There is absolutely no prospect that they will. The point is that the time is not ripe. Some day there will be a readjustment in prices to a level that will suit buyers, on the basis of the general liquidation that is now in progress. No readjustment to the eventual bottom could be made now, for it is still to be ascertained how far costs of production can be reduced, and even if the mills could name bottom prices now they would be quite indisposed to do so since buyers would not take hold freely at this time no matter what prices were named, and there is a tactical advantage in holding off from making reductions, or at any rate the last of the reductions that will have to be made.

### Wages

Possibly it is largely because mills do not consider it advantageous to reduce prices at this time that they are so slow in reducing wages. No employer pretends that wages should not come down, and by a large amount, yet less than half the independents, in point of capacity, have reduced wages to any noteworthy extent, while the Steel Corporation appears not even to have considered the matter. The steel producers doubtless feel that if there were such general reduction in wages buyers would at once clamour for much lower steel prices, and there might be more lost than gained. Particularly in the Pittsburgh and Youngstown districts wage reductions have been lacking, though of course there has been some reduction in wage costs, by less efficient men being let go, and by men previously drawing bonus or special wages being released, to be engaged afresh at standard rates.

### Prices and Costs

That there is room, eventually, for very considerable declines in prices is shown by the Steel Corporation's earnings reports. The year 1920 shows $177,000,000 earnings, after allowance for all taxes including the federal income and excess profits taxes, and after paying interest on bonds of subsidiary companies. That is 10 per cent. more than the corporation's earnings in the best year before the war and about two and one-half times the earnings in the poorest year. Yet the corporation was greatly handicapped in 1920. It had an average operation of only about 82 per cent., while in 1916 it had a 100 per cent. operation. Its costs were high on account of conditions in general, and there was the particular disadvantage that the costs rose to an extent by sympathy with the high costs of the independent mills, the latter caring little about costs since they advanced their selling prices. The corporation got nothing by increased selling prices but lost something by increased costs. The independents used to claim that they had to have their high prices because they were at a disadvantage by comparison with the Steel Corporation, and when pressed for particulars the chief item they mentioned was "overhead," just what before the war it used to be said distinguished the Steel Corporation. How the tables came to be turned so suddenly has never been satisfactorily explained. There is room for suspicion that many of the references to the high overhead of the independents included large dividends, bonuses, etc., in overhead. Now the independents are largely idle, and they are forced to lose the alleged overhead.

### Pig Iron and Coke

Valley foundry iron has become readily available at $30, furnace, or $1.50 decline, Bessemer and basic being altogether inactive and therefore remaining at $32 and $30 respectively. Most of the merchant furnaces are idle and the few in operation are facing the prospect of having to blow out.

The better balanced mentally of the merchant furnacemen are taking no interest in pig iron prices at this time. It is a matter of indifference whether the quotable market is one thing or another. What they are thinking of is costs. The costs will have to be reduced, there being confidence that when costs are made right the market will take care of itself. There is coke, for instance, now held at $6.00 as a contract price, though odd lots for spot shipment can be picked up at $5.00 or less. Two or three months ago the Connellsville coke operators were talking about holding out for one price or another, even prices higher than $10, and keeping their ovens idle until furnacemen should become willing to step up to the counter and buy at the seller's idea. Now the coke operators are hoping for reductions in costs. They need hardly anything but two things, contentment with lower profits and lower wage rates.

# BERTRAM AND PRATT & WHITNEY HELD THEIR SALES CONFERENCE

ON January 12, 13 and 14 the sales convention of the John Bertram and Pratt & Whitney Companies was held at Dundas, representatives being present from Montreal, New York, Halifax, Chicago, Winnipeg, Toronto, as well as a large number from Dundas.

This sales convention, which was a success in every way, was the first one held by the companies concerned, but it is the intention that it shall be an annual fixture in January of each year. Aside from the social part of the convention, which enabled the salesmen and managers to get better acquainted with each other and with the staff at Dundas, the papers and discussion which followed them in each case provided a valuable means for a free exchange of ideas, and enabled the salesmen to get the head office point of view and vice versa. The papers were, of course, all prepared in advance, and a bound copy of each paper was made by means of a duplicating machine, and placed in the hands of each person attending the convention, before the opening of the sessions, which gave each one a chance to look over the subject and become sufficiently acquainted with the paper to discuss it intelligently. Many of the papers were illustrated by lantern slides, which added considerably to the value of the papers as it enabled the speakers to illustrate points which could not otherwise have been made clear.

### Spoke of Earlier Days

A particularly interesting feature of the dinner on Thursday evening was Sir Alex. Bertram's address "Reminiscences," in connection with the founding of the Bertram plant by his father and the late Robert McKechnie. The dinner was held in the building which was lately the rectory of St. James Church, and the fact that the building was for many years the residence of the late John Bertram and the early home of Sir Alex. and Henry Bertram, recalled many incidents of the early days which stirred the emotions of every man present.

Wednesday, the first day of the conference, was largely taken up with tours of inspection to the Bertram and Pratt & Whitney plants, and the demonstration of certain machine tools, with descriptive addresses on these by A. W. Draeseke. Mr. Sprague, principal of Hamilton Technical School, was the speaker at the evening session.

Thursday morning papers were given by H. W. Angold, on some of the shop methods and inspection at the Bertram plant; G. H. Howard discussed enquiries, quotations and orders, from the viewpoint of the head office, while H. G. Bertram dealt with "Order Department Requirements." Helpful discussions fol-

# CARBONS *for electric arc welding*

THE ELECTRIC WELDING INDUSTRY has been tremendously advanced by the high development of arc carbons for specific purposes. We manufacture the following grades, named in the order of their current carrying capacities:

PLAIN WELDING CARBON:
A hard carbon for ordinary service.

COLUMBIA WELDING CARBON:
Very hard. It can also be furnished copper coated, making it suitable for use as a cutting electrode as well as for heavy welding work.

SPECIAL GRAPHITE WELDING CARBON:
Rather soft and graphitic. High conductivity. Used where a high amperage is required. Used with excellent results on general work.

# INDUSTRIAL NEWS

## NEW SHOPS, TENDERS AND CONTRACTS PERSONAL AND TRADE NOTES

## READY FOR THE EXPORT TRADE

**International Malleable at Guelph Put in Plant to Machine Castings**

The International Malleable Iron Company, Guelph, have installed, in an addition to their plant, complete equipment for the machining of their malleable and cast iron pipe fittings and malleable and gray iron castings. This plant has practically doubled in capacity in the last five years. The company's sales organization includes the following representatives: Halifax, Geo. D. Hatfield, Bedford Chambers; St. John, N.B., H. G. Rogers, 147 Prince William Street; Winnipeg, Harry F. Moulden & Son, Confederation Life Building; Vancouver, Cyril Ames, Wilton Block. The Toronto and Montreal fields are taken care of from the head office, Guelph. Arrangements are being made whereby the company will be capably represented in the development of fittings business in foreign markets.

## PLENTY OF ORDERS AT THIS PLANT

At the annual meeting of the Canadian Car and Foundry Company, W. W. Butler stated he had been disappointed in the showing for the past year, as he had expected to report greater profits. Business had been curtailed by strikes, the car embargo, and difficulties in obtaining material, with the result that only 1,700 cars had been turned out, despite large orders on the books. Most of the profits for the year were the result of the company's production of specialties. He pointed out in this connection that the company was the most self-contained car plant in the world, and manufactured more of its own requirements than any other plant in existence.

Fifty-five hundred cars had been carried over on the books, which exceeded any previous year. The company had on its books at the commencement of its present fiscal year orders in excess of $26,000,000, as compared with about $8,000,000 at the start of the previous year. At present the company has $14,000,000 in orders on its books, enough to keep the company going for some time.

## CHANGES MADE AT WILLYS-OVERLAND

**J. R. Marlow to be Secretary-Treasurer —Mr. Burt Goes to Syracuse**

Several changes have taken place in the personnel of Willys-Overland Limited. J. R. Marlow has been promoted from the position of Montreal branch manager to be secretary and treasurer of the company. As he will also have supervision of sales generally, Mr. Marlow will take over many of the duties formerly performed by Mr. MacKay and Mr. Dover. His appointment follows Mr. Burt's transfer to one of Overland's allied industries, the New Process Gear Company, of Syracuse, N.Y. When T. A. Russell, president of Willys-Overland Limited, announced the appointment of C. R. Burt as general manager, it was part of the arrangement with Mr. Willys and Mr. Chrysler that Mr. Burt would return to the United States later in the present year. Owing to developments earlier than expected, it was found advisable for Mr. Burt to assume the management of the gear company in January. Formerly sales manager of the Russell Motor Car Company in Toronto, Mr. Marlow went to Montreal in 1915 to take charge of the then Russell Motor Car Company branch. This branch was taken over as a branch of Willys-Overland Limited in 1917 and Mr. Marlow continued as manager.

J. R. MARLOW,

Appointed Secretary and Treasurer of the Willys-Overland Co., Toronto.

## NEW SALES FORCE NOW ORGANIZED

Considerable interest is being shown in the forthcoming organization of what will be known as the Dominion Industrial Products Co., Ltd. This concern will be the accredited Canadian representatives of some thirty or more United States manufacturers of numerous industrial products.

The products handled range from industrial railway equipment, and road contractors' equipment and supplies to various metal specialties, i.e., machine screws, bolts, nuts, washers, special nails, escutcheon pins and screw machine products in all metals. Non-ferrous metals, steel sheets, bars shapes, etc., will be dealt in, as also will certain types of foundry equipment and supplies.

It is not expected that warehouses will be maintained before the end of the year, but there are immediate prospects of sales offices being opened in the principal Canadian cities this year.

Those connected with the enterprise include W. P. Young, formerly general purchasing agent of the Canadian Edison Appliance Co., Ltd., of Stratford, and the Canadian General Electric Co., Ltd.; J. M. Young, formerly connected with the Russell Motor Car Co., Ltd., and the Machine & Stamping Co., Ltd. James W. Derbyshire will be general sales manager, and a fairly large sales staff will be engaged, as the Dominion Industrial Products Co., Ltd., is Dominion-wide in its scope.

## APPOINTED NOW AS SALES MANAGER

**G. F. Morris Started as an Apprentice Machinist with Business Machines**

Announcement has been made of the appointment of G. F. Morris to the position of sales manager of the time recording division of the International Business Machines Company, Limited, Toronto. Mr. Morris' connection with the company has extended over a period of ten years. He started as an apprentice machinist with the International Time Recording Company, Limited, in 1909 when International time recorders were first manufactured in Canada. When F. E. Mutton became general

# The Week's Events in Montreal Industry

The Dominion Bridge Company, of Montreal, held their second annual reception and dance at the Windsor Hotel last week, when about 600 were present, including the president, G. H. Duggan, and a number of directors and representatives from the branch offices and plants.

Owing to the falling off in orders the management of the Canadian Steel Foundries are contemplating the closing down of the Longue Pointe plant for a period of several weeks. The car division of the company's activities is fairly active but curtailment has been made in other departments.

The C. P. R. Angus shops in Montreal, are still working on the 8-hour 5-day schedule, with practically the same staff as before the holidays. A slight change has been made in respect to starting and stopping, the works opening one hour earlier on account of the increasing daylight.

At the forthcoming annual meeting of the Engineering Institute of Canada it is expected that J. M. R. Fairbairn, chief engineer of the C. P. R., will be elected to the office of president for the ensuing term, succeeding R. A. Ross, who retires at this time. Mr. Fairbairn has been connected with the head office of the C. P. R. in Montreal for the past twenty years.

One man, Alfred Robson, was killed, and three others seriously injured, by the explosion of a quantity of old flash powder thrown into the furnace at the plant of the National Drug Company in Montreal. The small quantity first thrown in flashed back and ignited the remainder held in the hands of Robson, who was also blown to pieces by the force of the explosion. Slight damage was done to the boiler and building.

The death of W. J. Moule, assistant comptroller of the Canadian Pacific Railway removed another well known official of the railway company. For three weeks before his death Mr. Moule suffered from sleeping sickness. Mr. Moule spent his entire career with the C. P. R., starting as a young office clerk back in 1891, and gradually advancing to more responsible positions until he became assistant comptroller in 1918.

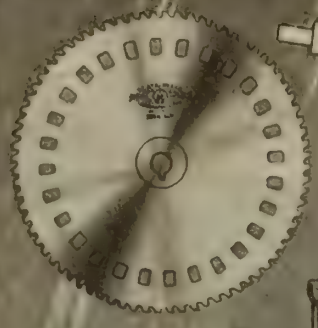
J. V. Robinson, inventor of the original Robinson train connector, has taken action against his brother, E. A. Robinson, of Montreal, for the marketing of a similar device, this, it is claimed, being contrary to agreement. E. A. Robinson claims that he severed his connection with the original company, and that the improved connector has been developed since that time, and that any restrictions placed upon it would be detrimental to the public interest. Judgment has been reserved.

An interesting demonstration of a forest tractor, manufactured by the Renault Company of France was given by H. Thiebaut, the Canadian agent in Montreal, before a number of engineers and interested parties, early this week in Montreal. The tractor is a modification of the war tank and is especially adapted to work in field and farm, forestry work and mountain transport, and the drawing of trucks and the towing of barges. A similar demonstration will be held, later in the week, before the representatives of the Montreal Harbor Commissioners.

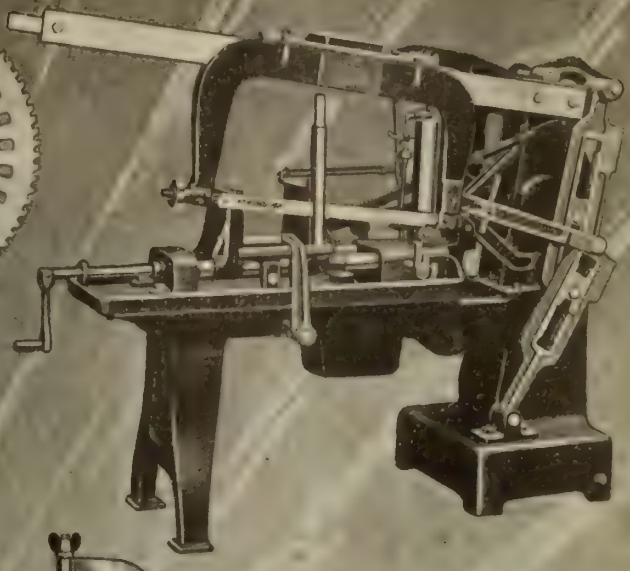
An interesting incident in connection with industrial inactivity was noted last week in Montreal, when a casual visit to the old plant of the John McDougall Caledonia Iron Works brought to light the fact that all the old patterns were being disposed of at the remarkably low figure of $3.50 per load. The McDougall firm went out of business about a year ago, and this industrial firm was one of the oldest of its kind in the Dominion. In the days of ascendancy this load of "firewood" would represent an outlay of tens of thousands of dollars.

The Blashill Wire Machinery Company of Montreal are looking for a location to establish a plant for the making of wire fencing. A. E. Blashill is the designer of a new type of fence making machine, and the company had contemplated a manufacturing move a couple of years ago, but owing to the difficulty of securing raw materials, the enterprise was temporarily abandoned, but with the conditions for the securing of wire product much improved, the plans are again under way, and it is expected that the company will be making fence before the early summer.

The eighteenth annual banquet of the Canadian Railway Club was held at the Windsor Hotel, in Montreal, on the last Saturday in January, and proved to be one of the best attended and most successful in the history of the club. The chair was occupied by W. H. Winterrowd, chief mechanical engineer of the C. P. R., and the speaker of the evening was the Hon. F. B. Carvell, chairman of the Board of Railway Commissioners. Other speakers were Dr. Stephen Leacock of McGill University; W. W. Butler, president of the Canadian Car and Foundry Company, and others. The entertainment committee provided an excellent program of musical and vaudeville talent.



This week will see the commencemen of the sittings in Montreal in connection with the arbitration boar which will decide the present value o the Grand Trunk Railway, and th amount the Canadian Government wil have to pay for the acquisition of th holdings of the road. It is expecte that the proceedings will occupy nearl three months. The Board will be pre sided over by Sir Walter Cassels, of th Exchequer Court of Canada; Sir Thos White will represent the Government and ex-president W. H. Taft will lool after the interests of the Grand Trunl shareholders. Associated with these will be a long array of lawyers, engineers and experts.



Speaking before the Canadian Railway Club, at their recent banquet the Hon. F. B. Carvell, chairman of th Board of Railway Commissioners, emphasized the fact that rates on railways whether private or Government owned must be sufficient to pay a reasonabl profit over and above operating expenses. "Only one set of rates can be use for all railroads," said Mr. Carvell. "You must face conditions as you find them The Government must consider the C.N R., as well as the C.P.R., and it is the duty of all public bodies to support the C.N.R. I was always opposed to it as many others were. But whether we favor Government ownership or not, we have it, and within a year more than half the railways in Canada will be under Government ownership. I am not so sure that it was necessary to take over the Grand Trunk, but we have these lines, and the people must face the situation. I would impress upon the employees of the national system that they must give the same efficient service as those of the C. P. R., forgetting the common idea of those serving Government owned businesses."

**New Power Plant.**—A Niagara River water works project, jointly controlled by the United States and Canada and utilizing all the power developed from the river, was proposed to the Federal Power Commission at Washington by Peter A. Porter, of Niagara Falls, and T. Kennard Thomson, of New York City. The project would include a dam across the gorge below the falls and a tunnel under Goat Island and practically would eliminate all other projects. Proponents of the plan claim that it would be more economic and efficient than a number of small projects.

# Selling British Made Goods in Canadian Market

## Strong Organization to Take Up Matter of Fraudulent Trademarks—Montreal Speaker Believes That Tide Has Turned, And Feeling of Stability in Values Can Bring Business Revival.

ANOTHER step in bringing the Montreal and Toronto branches of the Canadian Association of British Manufacturers and their representatives closer together was taken at the annual meeting of the Toronto branch at the King Edward Hotel on January 28. Greetings were brought from the Montreal branch by Messrs. F. I. Spielman and John E. Ritchie, first and second vice-presidents of the Montreal branch, and both the retiring president, Mr. Geo. A. Marshall, and the newly-elected president, Major John Harris, intimated that steps would be taken to extend the activities of the organization to other centres of the Dominion.

Following luncheon in the banquet room, at which Mr. George A. Marshall presided, Secretary Bunney read the minutes of the last annual meeting. Treasurer Sharpe reported on the financial condition, showing a favorable balance in the treasury. A number of necessary changes in the constitution were left to the council to dispose of, these having been practically agreed upon by the Montreal and Toronto branches.

### The President's Address

Mr. Marshall, in his annual report, gave a very thorough resume of the work of the association, both in Toronto and Montreal, the Montreal annual meeting having been held on January 21. The work of the two associations being reviewed in this manner gave a wider scope of the activities of the organization.

"The association," said Mr. Marshall, "which was established in the early part of 1919 on the initiative of H. M. Trade Commissioners in Montreal and Toronto, has now a membership of over 200 representatives of the British trade in the Dominion of Canada, which development is due to your branch council members, trade section committees, and the valued assistance rendered through the good offices of H. M. trade commissioners. As outlined in our last annual report, the association, as members, has been strengthened considerably by the Federation of British Industries, which is an extensive organization dealing with British manufactures all over the world. They are in touch with chambers of commerce and boards of trade in all industrial centres, and we cannot too highly credit them with appreciation of their valuable assistance this past year to our association both as regards useful correspondence exchanged, and in the manner our suggestions are dealt with. In order of reciprocity the position is now better to extend to them our knowledge

MAJOR JOHN HARRIS.

President Canadian Association of British Manufacturers. Came to Canada in 1914 and saw military service in the Great War, rising from lieutenant to major. Decorated by the President of France. Also in South African War. Keenly interested in British trade in Canada.

of any British firm desirous of purchasing in this country, and information relating to the Canadian markets. Several of our members when visiting England have called at their London office, 39 St. James St., S.W. 1, with very satisfactory results. In this connection alone it should be an incentive to double our membership, as the governing authority of such an enormous organization is, in time, bound to prove beneficial to our mutual interests.

### Central Office

For the purpose of co-ordinating the business of the Montreal and Toronto branches, especially in dealing with overseas correspondence, it was unanimously decided by your respective councils to establish a central office at 39 Richmond St. East, Toronto, which is now suitably furnished in order to afford greater convenience and accommodation for businessmen interested in British manufacturers, and who wish to get in touch with the Association.

### Excise Taxes

When the new excise taxes were enforced this association added its protest to those of other representative bodies, as a result of which modifications were made to advantage of the importers of British-made goods.

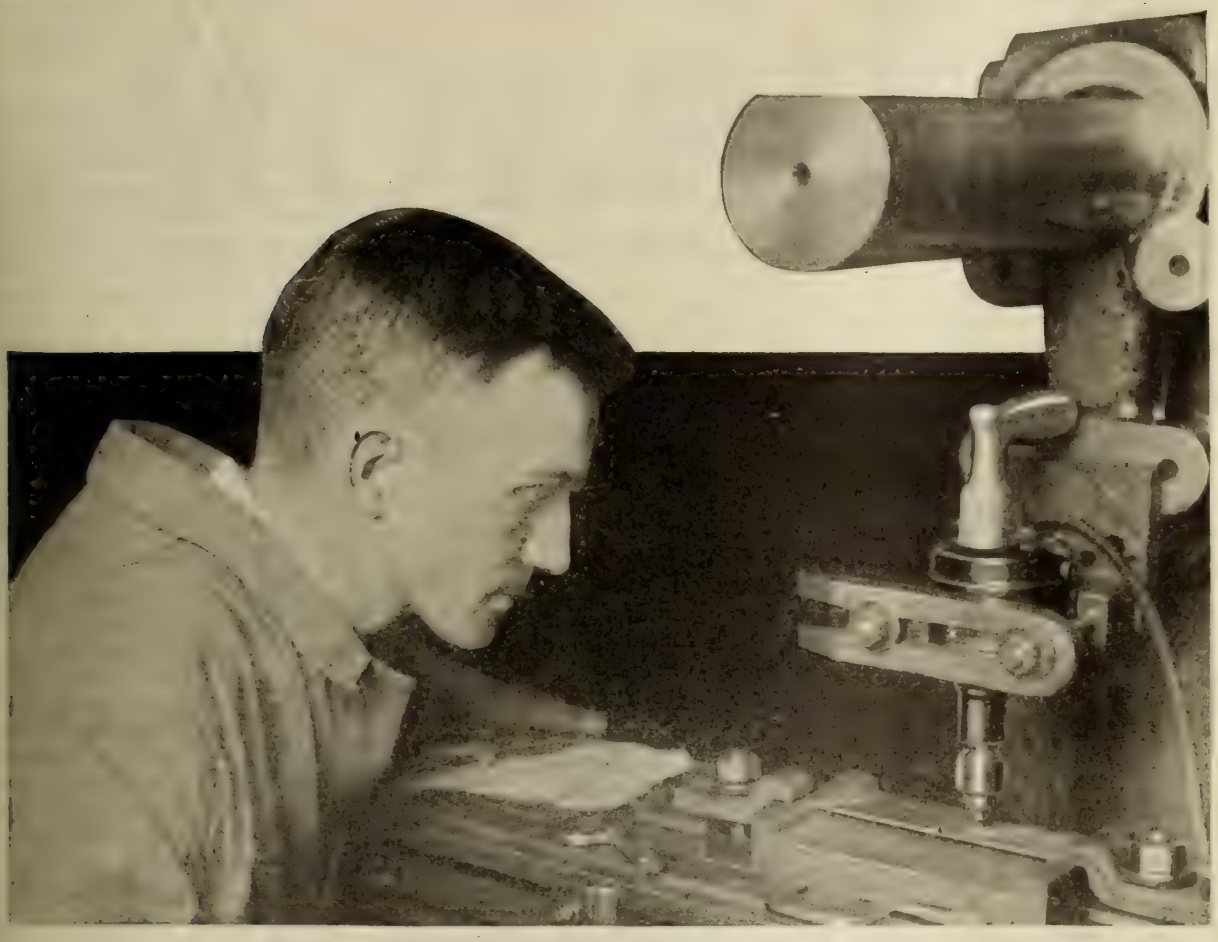
### Customs Valuation of Invoices

During the past year the question of the value of invoices for duty purposes arose, and in order to meet the suggestions from various members a deputation consisting of Montreal and Toronto branches waited upon the commissioner of customs at Ottawa, with the result that the authorities decided in July last to accept for the purpose of appraising duty the pound sterling at the current rate of exchange. This is one achievement which the members, their customers and the British exporter should appreciate, and I consider this action alone should justify the association's existence.

### Chamber of Commerce

A welcome was extended by this association to the deputation of the Allied Chamber of Commerce of the Empire who visited this Dominion in September last, and a communication was received from Lord Desborough, president of the Imperial Chamber, thanking the association and regretting the short duration of their stay with the many calls made upon the delegates would not permit of a special meeting being held.

### Meetings



During the year we held 17 branch council meetings, 14 trade section meetings and made three visits to Montreal council.

### Trade Sections

The trade sections are now well organized and show great improvement, especially the Textile section, consisting of the most members, with Harold Wilson as chairman. This section deserves special mention as it has been exceedingly active and of much assistance to the trade generally, inasmuch as it has provided for a Board of Arbitration to deal with disputes arising. They have also dealt satisfactorily with cases concerning cancellations and other important matters in the interest of every member connected herewith.

### Publicity Committee

The Publicity Committee, for which C. W. Beal is responsible, also must not be overlooked. A booklet entitled "Sales-Craft," published periodically by the association for the benefit of members and their principals, with the object of distributing broadcast, contains useful information. Two editions already have been prepared and printed, one dealing with the steel trade and the other with the textile trade, copies of which have been mailed to members and various overseas associations with a view of in-

# *Yankee Ingenuity Solves Drilling Problems with the Aid of this Dumore High Speed Drill*

John Bath & Company, Inc. (Worcester, Mass.)—maker of fine tools—uses a half dozen each of Dumore Drills and Grinders in his up-to-date shop.

The Photograph shows a Dumore Drill mounted on the overarm of a milling machine drilling holes in a tool steel jig plate 1/8" thick. There are 76 holes spaced .080" apart in several rows and a drill .051" in diameter is used.

Dumore Drills—like the well known Dumore Grinders—are accurately built, with an almost unlimited range of application. Used to supplement the work of big machines, Dumore High Speed Drills add to the capacity of the shop and cut production costs on many classes of work.

***Send for the details of Dumore High Speed Drills and Grinders. Let us show you how you can use them to advantage.***

**WISCONSIN ELECTRIC COMPANY,** 2932 Sixteenth Street - Racine, Wisconsin

# DUMORE PORTABLE DRILLS

creasing British trade in Canada and stimulating our aim.

### Advertising

Through the courtesy and good offices of H. M. trade commissioners we were enabled to exhibit at the Canadian National Exhibition last year advertising matter from various members of the association, and in addition, distribute 10,000 printed blotters advocating closer trade within the Empire and British-made goods. I should like to tender our thanks to H. M. trade commissioners in Canada for their sound advice and cheerful suggestions at all times given for the welfare of the Canadian Association of British Manufacturers.

### Appointments of Agents in U. S. for Canada

The association has taken up most energetically with the Federation of British Industries the question of appointment of agents in the United States for the Dominion of Canada. As evidence that this matter has received the attention it deserves, we would point out that during November last the matter was brought up in the British House of Commons. Whether any further action will be taken or not, attention has been called to this regrettable and inefficient policy.

### General

The question of the newspapers printing the times of departure of English mails in a prominent place, a request for the provision of late fee-boxes in Montreal, and the standardization of catalogues and printed matter of uniform size have all received careful attention of your councils.

No doubt you will be pleased to learn from the recent returns at Ottawa of the enormous increase during 1920 over 1919 in the imports from the United Kingdom to Canada. In the year 1919 only $87,659,198.00 worth of goods were brought in from the British Isles, whereas in 1920 the amount reads $231,479,294.00.

As ex-president I shall take my seat on the council of this branch for another year, during which time I shall endeavor to act with as much pleasure and interest as before, and give the council all the support possible, and in conclusion would like to express my grateful appreciation of the valuable assistance rendered me by your vice-president, Major John Harris, and the members of the council, with whom our business relationship has always been most friendly."

### Election of Officers

The election of officers resulted as follows:

President of both Montreal and Toronto branches, Major John Harris.

First vice-president of Toronto branch, C. W. Beal.

Second vice-president, Harold Wilson.

The president of the two organizations, Toronto and Montreal, is elected alternately from these places, the selection coming this year to Toronto as it had the greatest paid-up membership. Members of the Toronto council were elected as follows: Messrs. R. D. Harling, W. G. Patrick, W. Bruce Morrow, Arthur C. King, R. W. Paton, James Haywood and John Wilson.

President-elect Harris, on taking the chair, was given a hearty round of applause. In a few words he thanked the members for the honor shown him, paying a tribute to the pleasant relationships that had been formed with the other members of the council during his tenure of the office of vice-president.

Other business included the appointment of George A. Touche & Co. as auditors for the association, with Mr. Sharpe for the local organization.

Mr. John Wilson extended a welcome to the visitors from Montreal, assuring them of the desire of the Toronto branch to work closely in touch with them.

### Montreal Visitors Speak

Mr. F. I. Speilman, first vice-president of the Montreal branch, assured the gathering that he had felt the warmth of the Toronto welcome in a very real way, for when he left home it was ten below zero, and when he reached Toronto there were no signs of winter, "and I even noticed an absence of that white covering which is emblematic of the innocence and purity of Montreal." (Laughter). "I congratulate the new president and can promise him the support of the Montreal branch. There is a very desirable cohesion between the two organizations now. Formerly they were two, but now they are one, and we hope in the course of time to go ahead with further developments in other cities. The association is now recognized at Ottawa, and we had an opportunity to appear before the tariff commission a short time ago." Mr. Speilman also stated that they found it much easier getting appointments with the government at Ottawa now to present their views on various matters.

Mr. John E. Ritchie, second vice-president of the Montreal branch, pointed out that the textile men, especially during the last six months, had had some pretty serious times, but he believed the worst of it was over. He had words of counsel for the press of the country, claiming that they had in some cases led the public to expect larger reductions than were possible, although he was pleased to see they had mended their ways since. "Confidence is the main foundation of business," he stated, "and we believe it is being restored. In Montreal we are going out and asking for business now and we are getting it. What we need now is stability of prices. Any more reductions in textiles will have to be gradual. Prices took some six years to rise to present levels, and they are not going to come down overnight." Mr. Ritchie referred to a move that was being worked out by Mr. Wilson from Ottawa regarding duties from countries where money was at a discount or premium. The pound sterling was at a discount : he would add 20 per cent. or so to equa ize, and Canadian money being di counted in United States, there wou be a reduction of the discount, the resu being to reverse the British preferen in Canadian tariffs.

### Other Matters Discussed

Mr. Sturgeon brought up the matte of securing more publicity for Britis made goods, and also pointed out th the words British or England were ofte used on articles that never saw th country. "I have often seen goods marke 'Old English' that had never been mad in England."

President Harris said the council ha taken this matter up before, as sever complaints had been made, and the mat ter would be taken to Ottawa to fin out what could be done. He instance one article that was made in Phila delphia and marked "Old English." The were going to try and have such trad marks deleted. Mr. Speilman also re ferred to several instances in Montrea one very recently where a charge ha been made in the papers that Germa dyes in English packages were bein shipped to United States. This rumo they quickly denied by a letter to th English press of Montreal.

Before the meeting adjourned refer ence was made by several members t the work of Mr. George A. Marshall a president and also to the able assistanc of other officials.

## BERTRAM AND PRATT & WHITNEY HELD THEIR SALES CONFERENCE

Continued from page 86

lowed all these papers. Thursday after noon was opened by Mr. Leeds' addres on Niles, Bement, Pond products, fol lowed by Mr. Flaig on the Pratt & Whit ney lines. "Advertising" and "Branch Office Systems" were dealt with by C E. Dickson, Mr. Robb also giving a paper on the former subject. C. A. Fisher went into considerable detail on the de sign and manufacture of Pratt & Whit ney small tools. A dinner was held in the evening at which the address of Sir Alex. Bertram, referred to previously was the feature.

On Friday morning sales methods were discussed by M. B. Davidson and James Young, interest also being added by the presence of Mr. Smith, of Cleve land, who represented the Acme Ma chinery Company. The afternoon was also taken up with sales talks and a general review of the sales policy of the company.

## THE EFFECT OF RELATIVE HUMIDITY

(Continued from page 78)

If such an adjustment was made when the relative humidity was 20% and a subsequent change in the weather conditions produced a relative humidity of say 90%, while the power to be transmitted remained the same, it is apparent that the sum of the tensions must decrease. Since the difference in tensions remains the same while the sum decreases, it is evident that the ratio $T_1/T_2$ must increase. Fig. 6 shows this variation quite clearly, and at the higher humidities this ratio reaches a value where the belt is in great danger of slipping.

On the other hand, suppose that the belt was set to standard conditions when the relative humidity was 90% and subsequently the atmosphere dried. The belt would then become far too tight, not only working at too high a stress, but also producing excessive pressure on the bearings. Fig. 7 shows this effect very clearly.

If care were taken to allow for the effect of a change of the relative humidity, or if the adjustment were made when the humidity was 55% then no change of humidity that would occur would either tighten or slacken the belt in a degree that would be likely to give any trouble. Fig. 8 shows the effect on both the ratio and the sum of the tensions.

All of the preceding work is at a temperature of 70°F. and as the higher humidities are apt to occur at temperatures above 70° and the lower humidities below 70° it was thought best to extend the field of investigation by varying the temperature. Accordingly a series of experiments was made at 50°F. with the relative humidity varying from 20% to 90%. Another series with the temperature 90°F. was carried out.

The sum of the tensions, and also the horse power, was constant for all of these tests. The results of these tests are shown in Fig. 9, which also has the results for 70°F. from the previous experiments.

If a belt can be fitted with a spring or gravity tightener, so called, a load probably fifty per cent greater can be carried without danger of stretching the belt, slipping or excessive pressure on the bearings.

## Personal

Mr. Reeves, of John Inglis & Company, is in Europe on business in the firm's interests.

The death occurred of Thomas Worrell, aged 54, at his home, 39 Beverley Street, Toronto. Born in England, he had been in Canada since a boy. For the past twelve years he had been foreman of the machine shops at the Pendrith Machinery Company's works.

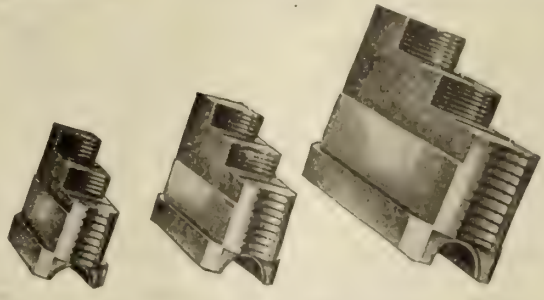
One of St. Catharines' esteemed residents and a valued employee of the Welland Vale Manufacturing Company passed away suddenly, Nicklin Nicholas Bulger. The deceased, who was in his 58th year, returned from work and shortly after was stricken and passed away. The late Mr. Bulger was born in Montreal, and came to this city as a boy. He had been an employee of the Welland Vale Manufacturing Company for the past thirty years and was superintendent of the plant.

H. E. Brasier is now Ontario sales manager of the Willys-Overland Company. He has been handling the service department since 1914. Mr. Brasier is a native of Peterboro but came to Toronto as a boy. His first work was with the Massey-Harris bicycle department and he was with the Canada Cycle & Motor Company from 1900 until 1904, when he joined the American Abell Engine and Thresher Company as chief accountant. He remained there until 1912, when he became accountant at the Toronto branch of the Russell Motor Car Company.

### APPOINTED NOW AS SALES MANAGER

(Continued from page 90)

manager of the International Time Recording Company in 1915 Mr. Morris was placed in charge of the time recorder service department at Montreal. It was here that he graduated as a salesman and after a short time spent in Montreal and Toronto in this capacity was appointed sales agent for time recorders in Manitoba and Saskatchewan. At the time the International Business Machines Company, Limited, was organized in 1917, comprising the International Time Recording Company, Dayton Computing Scale Company and Tabulating Machine Company, Mr. Morris made a study of the tabulating machine business and was appointed subsequently representative of this branch of the company's interests in Western Canada. In August of last year he was called to the head office in Toronto to assume the duties of assistant to Mr. Mutton, vice-president and general manager.



His appointment as sales manager of the time recorder division was announced at the convention which the company held January 3-8.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

The Jaws Are Extra Strong

THEY are drop forgings, made of best quality steel, heat-treated and hardened. The threaded portion of jaws form a half nut for the setting-up screws. Have stood the test of heavy duty work in our own shops where accuracy was the only accepted standard.

"Yes, sir, and there's a good reason for it too. Since we installed the BOWSER Oil Filtering Outfit the men in the engine room have been competing to see who could save the most oil. They've cleaned the journal boxes, put pans under them to catch the drips and then put the salvage through the BOWSER Oil Filtering Outfit. We are now using the oil over and over again that was formerly wasted."

The BOWSER Oil Filtering Outfit is simple, compact, economical and reliable.

**Bowser 7F Oil Filter**

First, means a cleaner engine room.

Second, it cuts your lubricating oil bill considerably.

Third, IT PAYS FOR ITSELF over and over.

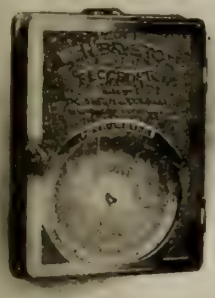
# Would You Like to make some Extra Money?

Of course you would. Well then, why not do so? Canadian Machinery is always on the lookout for well-worth-while ideas, and are willing to pay a good price for them.



We are often asked, "What sort of ideas do you want?" Briefly, what we are desirous of obtaining is this, "Any idea that has proved of value in the machine shop, drafting room, or tool room." Think of how you got over some difficulty, a ticklish piece to hold in the lathe, or perhaps how you increased production on some particular piece. Any idea that saves time or money in the machine industry will appeal to us. Never mind the style. Write it as best you know how. We will put the finishing touches to both the wording and the sketch. Start in **NOW** and send us something of such a nature.

Franklin Die-Castings Used in Farm Machinery

## *Improving Farm Methods*

THE Franklin Die-Casting Process has contributed its share to the advancement of living and working conditions on the farm. Die-Castings have simplified and reduced the cost of many parts for tractors, trucks, incubators, cow-milkers, separators and other devices which have helped establish the modern standard for farm life.

In 1892 we originated the Die-Casting Process and we have for nearly thirty years aided in the development of many fields of industry.

Send us samples or blueprints and we will give you quotations on castings in Aluminum, Tin, Lead or Zinc base alloys.

Write for booklet, "Franklin Die-Castings in Many Fields."

# THE NEW LANDIS AUTOMATIC DIE HEAD

The new Landis Automatic Die Head for application to Screw Machines and Turret Lathes is now placed upon the market to handle your threading jobs in the efficient Landis style.

This head is made in the 1¼″ and 2″ sizes. It may be equipped for cutting bolt, pipe or special threads. It is furnished with a shank to fit your requirements. This Automatic Head is entirely different in design from any head of its type. It embodies features which made the Landis Rotary Head famous. Consider the following:—

1. Chasers and holders are located on face of head which permits of quick and easy adjustment.
2. Rough and finishing cuts may be taken by merely a turn of the latch.
3. Right and left hand threads can be cut on the same head with same chasers by using right and left hand chaser-holders.
4. Fine adjustments quickly made by simply turning graduated adjusting worm.
5. Positive locking mechanism insures correct size at all times.
6. All adjustments are made on outside of head.
7. No dirt or chips can enter inside of head.
8. Fewer parts enter into this head than any other make.
9. Head is made of steel, is rigid in design and simple in construction.
10. This head employs Landis Chasers which are interchangeable with chasers on the Landis ½″ Rotary Die Head.

*It will pay you to install this head. Write for description and send specifications.*

Thor

## PNEUMATIC and ELECTRIC TOOLS

When you put THOR Tools on your work you are not "trying them out." Every minute mechanism in THORS is tried, tested, improved and perfected before it comes to you. All left for you is to decide, with the assistance of our expert mechanical department, the tool best adapted to your particular work. Hundreds of plants, knowing the reliability and tested merit of THORS, have adopted them as standard equipment.

# OAKITE CLEANS!

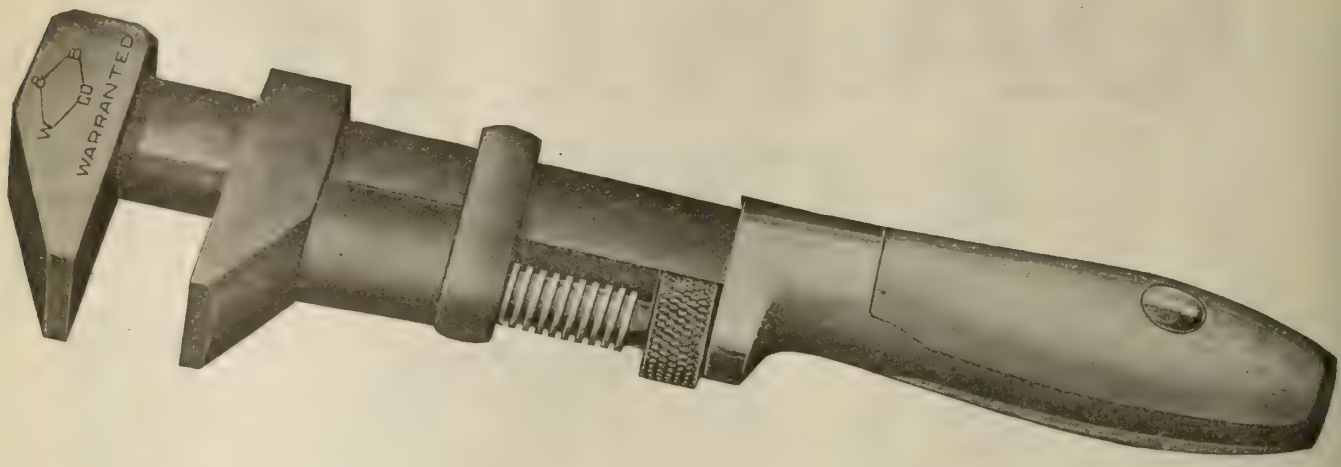
## *Oakite Cuts Cleaning Material Costs in Half*

THIS Tool Factory recently adopted Oakite materials for cleaning pliers (wire cutters) before pickling and plating, for the following reasons:

The oil, milling compound, rust and scale, removed in one hour instead of 1½ hours formerly required.

¾ lb. Oakite material cleans each lot of 100 pliers more satisfactorily than 1½ lbs. chip soap previously used.

The pliers are now put through cleaning operation at a saving in materials averaging ***one-half former cost.***



This advertisement is one of a series based on actual occurrences. n. w.

Results: Formerly impossible to avoid discoloration after plating around center bolt and nut in pliers. This weakness now eliminated. Production is speeded up by cut in cleaning time. Desirable saving in cleaning costs is effected.

***May We Serve You, Too?***

**OAKITE** MANUFACTURED BY
OAKLEY CHEMICAL CO.

*If interested tear out this page and place with letters to be answered.*

"W & B" Screw Wrenches are dependable tools for the heaviest duty because into each of their parts is put the skill and experience—the "know how"—gained during nearly half a century of wrench manufacture.

They contain no weak member. With head and bar drop-forged in one piece from specially selected steel, extra heavy jaw thoroughly case-hardened and an accurately made, solid steel screw, each part contributes its individual share toward the assured, dependable strength of the complete tool.

Two models—"Railroad Special," with malleable iron handle, and Machinists' Knife Handle (illustrated above) are the strongest and best heavy duty screw wrenches made. Six sizes—6 to 21 inches.

A third model—"Agricultural"—is supplied at a lower price where the maximum of strength and service is not necessary. Five sizes—6 to 15 inches.

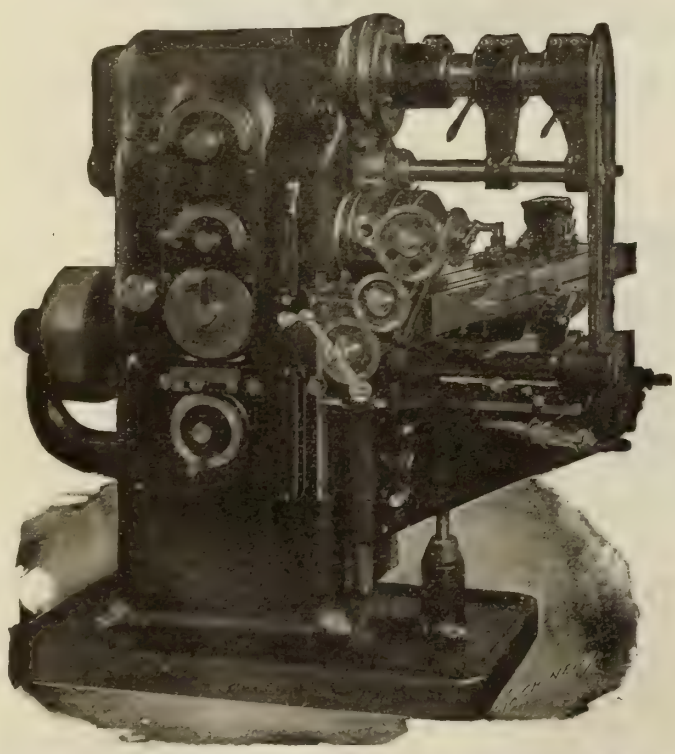
# Buried in the Work and Broke!

Next time a tap breaks below the surface of a large casting, don't let some makeshift method of removing it injure the thread and waste half an hour of valuable production time. Instead—

## Walton it Out in a Jiffy

And save the casting.



Special analysis steel fingers of the Walton Extractor drop into the flutes of the broken tap—and grip. Then a few turns of a wrench applied to the squared end of the Extractor backs out the buried tap.

**Sixty-day trial offer** proves the Walton Extractor pays for itself.

Write.

**The Walton Co.**
Hartford, Conn.

*For work requiring the utmost accuracy—*

# ROCKFORD MILLERS

have established an enviable reputation among prominent manufacturers for accuracy, simplicity in construction and ease of operation. That they have been able to do this is credited to the great care exercised in their design, and the high-grade workmanship used in their construction.

All feeds on the Rockford are controlled by one lever — the main spindle is instantly adjustable by a single nut, and the operator can complete a job without leaving the front of his machine. These are a few of the points that have made the Rockford a favorite with the men as well as their employers. We would like to tell you more about these machines. Write us for full information.

# HOLES for 1921

## Will Be Drilled Faster and Truer

with

# CANADIAN-DETROIT TWIST DRILLS

CUT down the cost per hole by specifying them on your next order.

We make milled drills of all types and sizes.

We also manufacture the famous DD rolled drills, in all sizes from ½ inch to 1½ inches, specially designed for drilling drop forgings and hard alloy steel castings. The Double-D combines the strength of the forged drill with the accuracy and uniformity of the milled type. The rolling process, which we control exclusively, gives greater density to the steel, without introducing the rough inaccuracies of hammering. Try DD drills on the toughest operation in your plant and watch them "hog in."

*We invite comparative tests.*

# *Not* cheaper drills— but cheaper *drilling!*

LOWER-COST-PER-YEAR performance records prove that for length of service and over-all operating economy, Little Giant Portable Electric Drills *stand alone.*

The same design that withstands the severe strains of shipyard and other heavy drilling service, is duplicated in *every* Little Giant, large or small.

Big-calibre engineering design necessary to meet big-user demands for productive efficiency, benefits *alike* the small shop, factory or assembly plant.

Whether you use one or one hundred Little Giants, each drill is backed by *direct personal-touch* service, with stocks of new tools and spare parts at Company Branches. This service "keeps drills drilling."

Little Giant Electric Tools are made for operation on any current and in many sizes and types. Ask for Booklet 397.
